# **1** Introduction and Document Description Rules

# 1.1 Introduction

This user manual provides application developers with all the information about how to use MCU (micro-controller) system architecture, memory and peripherals.

For information about Arm<sup>®</sup> Cortex<sup>®</sup>-M3 core, please refer to Arm<sup>®</sup> Cortex<sup>®</sup>-M3 technical reference manual; please refer to the corresponding datasheet for detailed data such as model information, dimension and electrical characteristics of the device; for all MCU series models, please refer to the corresponding data manual for memory mapping, peripheral existence and their number.

It is hereby declared that Geehy Semiconductor Co., Ltd., hereinafter refer to as "Geehy".

# **1.2 Document Description Rules**

# 1.2.1 "Register Functional Description" Rules

- (1) Control (CTRL) registers are all "set to 1 and cleared by software", unless otherwise specified.
- (2) The control registers are usually followed by verb abbreviations to make a distinction. The verbs can be: EN-Enable, CFG-Configure, D-Disable, SET-Setup and SEL-Select
- (3) The state register abbreviation is usually followed by FLG to make a difference.
- (4) The value and data registers usually include V, VALUE, D and DATA, which are not followed by verbs, such as: xxPSC and CNT.

Table 1 Abbreviation and Description of R/W Modes

# **1.2.2** Full Name and Abbreviation Description of Terms

| R/W mode   | R/W mode Description  |       |  |
|--|---|-------|--|
| read/write Software can read and write this bit. |   | R/W   |  |
| read-only  | Software can only read this bit.                                  | R     |  |
| write-only                                       | Software can only write this bit, and after reading this bit, the | W     |  |
| write-only                                       | reset value will be returned.                                     | vv    |  |
| read/clear                                       | The software can read this bit and clear it by writing 1. Writing | RC_W1 |  |
| Tead/clear                                       | 0 has no effect on this bit.                                      | RC_WI |  |
| read/clear                                       | The software can read this bit and clear it by writing 0. Writing | RC W0 |  |
| Tead/clear                                       | 1 has no effect on this bit.                                      | NC_W0 |  |
| read/clear by read                               | The software can read this bit, reading this bit will             | RC R  |  |
| reau/clear by reau                               | automatically clear it to 0, and writing this bit is invalid.     | NC_N  |  |
| read/set   | The software can read and set this bit, and writing 0 has no      | R/S   |  |
| reau/Set   | effect on this bit.   | N/3   |  |
| road only write trigger                          | The software can read this bit and writing 0 or 1 can trigger an  |       |  |
| read-only write trigger                          | event but has no effect on the value of this bit.                 | RT_W  |  |

| R/W mode | Description  | Abbreviation |
|----------|--|--------------|
| togglo   | The software can flip this bit only by writing 1 and writing 0 has | т            |
| toggle   | no effect on this bit.   | I            |

# Table 2 Functional Description and Full Name and Abbreviation of Terms of Commonly Used Registers

# 2.2 System Architecture Block Diagram

The main system consists of four driving units and four passive units. The four driving units are DCode bus (D-bus), system bus (S-bus) and general DMA, which are connected to Arm<sup>®</sup> Cortex<sup>®</sup>-M3 core. The four passive units are internal SRAM, internal flash memory, EMMC and bridge from AHB to APB (AHB/APBx). AHB/APBx connects all APB devices.

These are connected through a multi-level AHB bus architecture, as shown in the figure below:

## Figure 1 System Architecture of APM32F103x4x6x8xB Series Products

Note: The number of different types of products contain modules, specific see datasheet.

# 2.3 Memory Mapping

The memory mapping address is totally 4GB address. The assigned addresses include the core (including core peripherals), on-chip Flash (including main memory area, system memory area and option bytes), on-chip SRAM, EMMC and bus peripherals (including AHB and APB peripherals). Please refer to the data manual of the corresponding model for specific information of various addresses.

# 2.3.1 Embedded SRAM

Built-in static SRAM. It can access by byte, half word (16 bits) or full word (32 bits). The start address of SRAM is 0x2000 0000.

# 2.3.2 Bit Band

Arm<sup>®</sup> Cortex<sup>®</sup> -M3 memory is mapped with two bit-band areas, and it maps each word in the alias memory area to a bit in the bit-band memory. Write a word to the alias memory and there will be the same effect as the read-changewrite operation on the target of the bit-band area. Both peripheral register and SRAM are mapped into a bit band area, and it is allowed to perform single bitband write and read operations.

The following gives a mapping formula:

bit\_word\_addr=bit\_band\_base+ (byte\_offset×32) + (bit\_number×4)

Please see Arm® Cortex®-M3 Technical Reference Manual for details

# 2.4 Startup Configuration

Since the CPU of Arm<sup>®</sup> Cortex<sup>®</sup>-M3 core CPU obtains reset vector from ICode Bus (instruction bus), the startup can only start from the code area, and the typical is Flash memory boot. However, APM32 MCU series realizes a special mechanism. By configuring the BOOT[1:0] pin parameters, there are three different startup modes, namely, the system can not only start from Flash memory or system memory, but also start from the built-in SRAM. The memory selected as the start zone is determined by the selected startup mode.

| Startup mode selection pin |       | Startup mode                 | Access mode  |
|----------------------------|-------|------------------------------|--|
| BOOT1                      | BOOT0 |                              |  |
| x                          | 0     | Main flash memory<br>(Flash) | The main flash memory is mapped to the boot<br>space, but it can still be accessed at its<br>original address, that is, the contents of the<br>flash memory can be accessed in two<br>address areas. |
| 0                          | 1     | System memory                | The system memory is mapped to the boot space (0x0000 0000), but it can still be accessed at its original address.   |
| 1                          | 1     | Built-in SRAM                | SRAM can be accessed only at the starting address.   |

 Table 5 Startup Mode Configuration and Access Mode

Note:

- (1) The boot space address is  $0x0000\ 0000$
- (2) The original address of Flash is 0x0800 0000
- (3) The original address of system memory is 0x1FFF F000
- (4) The starting address of SRAM is 0x2000 0000

The user can select the startup mode after reset by setting the states of BOOT1 and BOOT0 pins. BOOT pin should keep the user's required startup configuration in standby mode. When exiting from the standby mode, the value of boot pin will be latched.

If you choose to start from built-in SRAM, you must use NVIC's exception table and offset register to remap the vector table to SRAM when writing the application code.

# Embedded startup program

The embedded startup program is written on the production line by Geehy and stored in the system memory area; the Flash memory can be reprogrammed by using USRAT1 to enable the startup program.

# 3 FLASH Memory

This chapter mainly introduces the storage structure, read, erase, write, read/write protection, unlock/lock characteristics of Flash, and the involved register functional description.

# 3.1 Full Name and Abbreviation Description of Terms

| Table 6 Full Name | and Abbreviation | Description | of Terms |
|-------------------|------------------|-------------|----------|
|                   |                  | Description |          |

| Full name in English    | English abbreviation |
|-------------------------|----------------------|
| Flash Memory Controller | FMC                  |

# 3.2 Main Characteristics

- (1) Flash memory structure
  - Contain main memory area and information block
  - The capacity of main memory area is up to 128KB
  - The information block is divided into system memory area and option byte
  - The capacity of the system memory area is 2KB, for storing BootLoader program, 96-bit unique UID, and main memory area capacity information
  - The capacity of the option byte area is 16Bytes
- (2) Functional Description
  - Read Flash
  - Page/mass erase Flash
  - Write Flash
  - Read/Write protection Flash
  - Configure option bytes

# 3.3 Flash Memory Structure

### Table 7 Flash Memory Structure of APM32F103x4/x6/x8/xB Series Products

| Block                         | Name               | Address area            | Size (byte) |
|-------------------------------|--------------------|-------------------------|-------------|
| Main memory area              | Page 0             | 0x0800 0000–0x0800 03FF | 1K          |
| Main memory area              | Page 1             | 0x0800 0400–0x0800 07FF | 1K          |
| Main memory area              | Page 2             | 0x0800 0800–0x0800 0BFF | 1K          |
| Main memory area              | Page 3             | 0x0800 0C00-0x0800 0FFF | 1K          |
| Main memory area              |                    |                         |             |
| Main memory area              | Page 127           | 0x0801 FC00-0x0801 FFFF | 1K          |
| Information block             | System memory area | 0x1FFF F000–0x1FFF F7FF | 2K          |
| Information block Option byte |                    | 0x1FFF F800–0x1FFF F80F | 16          |

Note: The number of pages in the main memory block of APM32F103x4/x6/x8/xB series products is related to the Flash capacity of specific product.

# 3.4 Flash Memroy Functional Description

Describe the operation of main memory and information block (including system memory area and option byte), including read, write, erase and read/write protection.

Reading Flash includes main memory block and information block, while the erase, write, read/write are introduced separately; the system memory area has been written before the product leaves the factory and cannot be modified by the user. The erase, write, and read/write protection of the module will not be introduced.

### 3.4.1 Read Flash

Flash memory can be directly addressed, and reading Flash is affected by the following configuration:

### Wait cycle

Different waiting cycles should be configured for different system clocks:

- 0 wait cycle: 0<system clock≤24MHz
- 1 wait cycle: 24MHz<system clock≤48MHz
- 2 wait cycles: 48MHz<system clock≤72MHz
- 3 wait cycles: 72MHz<system clock≤96MHz

### **Prefetch buffer**

It can improve the reading speed and every time it is reset, the prefetch buffer will be automatically opened; the read interface with prefetch buffer is 2×64 bits for APM32F103x4x6x8xB series. It can be configured only when the system clock is consistent with AHB clock and is less than 24MHz, and can be used only when the system clock is consistent with AHB clock.

### Half-cycle access

When the power consumption needs to be optimized, half-cycle access can be used; at this time, Only the system clock and AHB clock consistent and system clock less than 24 MHZ to configure open or closed.

### 3.4.2 Main Memory Block

### 3.4.2.1 Erase main memory block

FMC supports page erase and mass erase (full erase) to initialize the contents of the main memory area to high level (the data is represented as 0xFFFF). Before writing to Flash, users are advised to erase the write address page. If the data of write address is not 0xFFFF, a programming error will be triggered.

### Main memory page erase

Page erase is an independent erase according to the main memory area page selected by the program, which will not have any impact on the page not selected for erasure.

After the correct page erase (or Flash write operation) is completed, OCF of FMC\_STS register will be set. If OCIE interrupt is enabled, an operation completion interrupt will be triggered. Users need to note that the page to be erased must be a valid page (the valid address of the main memory area and the address without write protection).

### Main memory mass erase

The mass erase operation will erase all the contents in the main storage area of Flash, and the mass erase operation will erase all the data in the main memory area, so the users need to pay special attention when using it to avoid the loss of important data caused by misoperation.

### 3.4.2.2 Main memory block of write

FMC supports the writing of 16-bit (half word) data in the main memory area. You can select Debug, BootLoader, program running in SRAM, and directly reading the erased page to judge whether the erasing is successful.

In order to ensure correct writing, it is necessary to check whether the destination address has been erased before writing; if it is not erased, the written data will be invalid and PEF bit of FMC\_STS register will be set to "1". If the destination address has write protection, the written data is invalid and a write protection error will be triggered (WPEF bit of FMC\_STS is set to "1").

### 3.4.2.3 Main memory block of read/write protection

Read/write protection of the flash is used to prevent illegal reading/modification of the main memory area code or data, and it is controlled by the read/write protection configuration byte of option byte. For APM32F103x4x6x8xB series products, the basic unit of read/write protection is 4 pages (i.e. 4KBytes).

### **Read protection**

Internal Flash protection level can be set by modifying the value of option byte READPROT. The debugger is always connected to JTAG/SWD interface to set read protection, which takes effect after power-on reset; otherwise, it will not take effect after the system is powered on and reset. When the READPROT value is any value except 0xA5, enable read protection and the content of main memory block cannot be read; when the READPROT value is 0xA5, the protection is released and the content of main memory block can be read; when the read protection is removed, a main memory mass erase operation will be triggered to prevent illegal read after the protection is degraded.

### Write protection

Write protection control can be conducted for the corresponding page of the main memory block by configuring the value of write protection option byte WRP0/1/2/3. After the write protection is turned on, the content on the corresponding page of the main memory area cannot be modified in any way.

### 3.4.2.4 Main memory block of unlock/lock

FMC\_CTRL1 of the reset FMC will be locked by hardware, and then FMC\_CTRL1 can't be directly written, and the corresponding value must be written to FMC\_KEY according to the correct sequence to unlock FMC. The KEY value is as follows:

- KEY1=0x45670123
- KEY2=0xCDEF89AB

The wrong writing sequence or wrong value will cause the program to enter the hardware wrongly. At this time, FMC will be locked, and all FMC operations will be invalid until it is reset next time. The users can also lock FMC through software by writing "1" to LOCK bit of the control register 2 (FMC\_CTRL2).

In each Flash programming operation, the users must follow the steps of "Flash unlock - program by user - Flash lock", so as to avoid the risk that user code/data is accidentally modified due to the Flash unlocking after the Flash

programming operation.

# 3.4.3 Option Byte

### 3.4.3.1 Erase option byte

Support erase function. After the correct option byte erase (or option byte write operation) is completed, OCF of FMC\_STS register will be set. If OCIE interrupt is enabled, an operation completion interrupt will be triggered.

### 3.4.3.2 Write option byte

Eight configurable bytes of option bytes all support writing function.

### 3.4.3.3 Write protection of option byte

Defaultly, the option byte is always readable and write protected. To perform write operation (program/erase) for the option byte block, first write the correct key sequence (the same as that of locking) in FMC\_OBKEY, and then allow the write operation of option byte block; the OBWEN bit of FMC\_CTRL2 register indicates write enabled; clear this bit and write operation will be disabled.

### 3.4.3.4 Unlock/Lock option byte

After the system reset, the option byte is locked by default. Only when the option byte is unlocked correctly, can it be modified. The difference between option byte unlocking and flash unlocking is that FMC\_OBKEY register rather than FMC\_KEY register writes the KEY value. The option byte does not support "software lock". The user should pay special attention to that every time after the value of the option byte is modified, the system must be reset to make it effective.

# 3.5 Option Byte Register Functional Description

The option byte provides some optional functions for users, and it mainly consists of 8 configurable bytes and corresponding complementary codes. Every time the system is reset, the option byte area will be reloaded to the FMC\_OBCS and FMC\_WRTPROT register (the option byte will only take effect each time they are reloaded to FMC). In the process of reloading, if a certain configurable byte does not match its inverse code, an option byte error (OBE bit of FMC\_OBCS register is set to "1") will be triggered, and this byte will be set to "0xFF". The information of 16 bytes in the option byte area is shown in the table below.

| Address     | Option byte | Initial<br>value | R/W | Functional description   |
|-------------|-------------|------------------|-----|--|
| 0x1FFF F800 | READPROT    | 0xA5             | R/W | Read protection configuration  |
| 0x1FFF F801 | nREADPROT   | 0x5A             | R   | READPROT complementary code  |
| 0x1FFF F802 | UOB         | 0xFF             | R/W | User option byte<br>Bit 0: WDTSEL<br>0: Hardware watchdog<br>1: Software watchdog<br>Bit 1: nRSTSTOP<br>0: Reset occurs when entering the<br>Stop mode<br>1: Reset does not occur when<br>entering the Stop mode<br>Bit 2: nRSTSTB |

Table 8 Option Bytes

| Address     | Option byte | Initial<br>value | R/W | Functional description  |
|-------------|-------------|------------------|-----|---|
|             |             |                  |     | 0: Reset occurs when entering the<br>Standby mode<br>1: Do not generate reset bit [3:7] when<br>entering Standby mode: Reserved |
| 0x1FFF F803 | nUOB        | 0x00             | R   | UOB complementary code  |
| 0x1FFF F804 | Data0       | 0xFF             | R/W | User data byte 0  |
| 0x1FFF F805 | nData0      | 0x00             | R   | Data0 complementary code  |
| 0x1FFF F806 | Data1       | 0xFF             | R/W | User data byte 1  |
| 0x1FFF F807 | nData1      | 0x00             | R   | Data complementary code   |
| 0x1FFF F808 | WRP0        | 0xFF             | R/W | Write protection configuration 0  |
| 0x1FFF F809 | nWRP0       | 0x00             | R   | WRP0 complementary code   |
| 0x1FFF F80A | WRP1        | 0xFF             | R/W | Write protection configuration 1  |
| 0x1FFF F80B | nWRP1       | 0x00             | R   | WRP1 complementary code   |
| 0x1FFF F80C | WRP2        | 0xFF             | R/W | Write protection configuration 2  |
| 0x1FFF F80D | nWRP2       | 0x00             | R   | WRP2 complementary code   |
| 0x1FFF F80E | WRP3        | 0xFF             | R/W | Write protection configuration 3  |
| 0x1FFF F80F | nWRP3       | 0x00             | R   | WRP3 complementary code   |

Note: When the configurable byte and its complementary value are "0xFF", the match will not be verified in the reloading process

| Product capacity                              | Functional description   |  |
|---|--|--|

Table 11 Full Name and Abbreviation Description of Terms

# 4.2 Reset Functional Description

The supported reset is divided into three forms, namely, system reset, power reset and backup area reset.

# 4.2.1 System Reset

### 4.2.1.1 "System reset" reset source

The reset source is divided into external reset source and internal reset source.

External reset source:

• Low level on NRST pin.

Internal reset source:

- Window watchdog termination count (WWDT reset)
- Independent watchdog termination count (IWDT reset)

- Software reset (SW reset)
- Low-power management reset
- Power reset

A system reset will occur in case of any of the above events. Besides, the reset event source can be identified by viewing the reset flag bit in RCM\_CSTS (control/state register).

Generally speaking, when the system is reset, all registers except the registers in RCM\_CSTS (control/state register) reset flag bit and backup area will be reset to the reset state.

### Software reset

Software can be reset by putting SYSRESETREQ in Arm® Cortex®-M3 interrupt application and reset control register to "1".

### Low-power management reset

Low-power management may reset in two cases, one is when entering the standby mode, and the other is when entering the stop mode. In these two cases, if RSTSTDB bit (in standby mode) or RSTSTOP bit (in stop mode) in user selection byte is cleared, the system will be reset rather than entering the standby or stop mode.

For more information about user option bytes, refer to "Flash memory".

### 4.2.1.2 "System Reset" reset circuit

The reset source is used in the NRST pin, which remains low in reset process.

The internal reset source generates a delay of at least 20µs pulse on the NRST pin through the pulse generator, which causes the NRST to maintain the level to generate reset; the external reset source directly pulls down the NRST pin level to generate reset.

The "system reset" reset circuit is shown in the figure below.

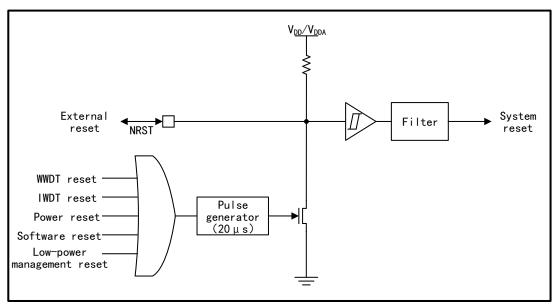

Figure 2 "System Reset" Reset Circuit

# 4.2.2 Power Reset

### "Power reset" reset source

"Power reset" reset source is as follows:

- Power-on reset (POR reset)
- Power-down reset (PDR reset)
- Wake up from standby mode

A power reset will occur in case of any of the above events.

Power reset will reset all registers except that in backup area.

# 4.2.3 Backup Domain Reset

### "Backup domain reset" reset source

"Backup domain reset" reset source is as follows:

- Software reset, set BDRST bit in RCM\_BDCTRL
- $V_{DD}$  or  $V_{BAT}$  is powered on when  $V_{DD}$  or  $V_{BAT}$  is powered down

A backup domain reset will occur in case of any of the above events.

The backup area reset has two special resets, which only affect backup area.

# 4.3 Functional Description of Clock Management

Clock sources of the whole system are: HSECLK, LSECLK, HSICLK, LSICLK, PLL. For the characteristics of the clock source, please refer to the relevant chapter of "Electrical Characteristics" in the data manual.

# 4.3.1 External Clock Source

The external clock signal includes HSECLK (high-speed external clock signal) and LSECLK (low-speed external clock signal).

There are two kinds of external clock sources:

- External crystal/ceramic resonator
- External clock of user

The hardware configuration of the two kinds of clock sources is shown in the figure below.

| Clock source                 | Hardware configuration   |
|------------------------------|--|
| External clock               | OSC_IN_OSC_OUT<br>(Hiz)<br>External clock source   |
| Crystal/ceramic<br>resonator | $\begin{array}{c c} & & & \\ & & & \\ & & & \\ \hline \\ \hline$ |

### Figure 3 HSECLK/LSECLK Clock Source Hardware Configuration

In order to reduce the distortion of clock output and shorten the start-up stabilization time, the crystal/ceramic resonator and load capacitor must be as close to the oscillator pin as possible. The value of load capacitance ( $C_{L1}$ ,  $C_{L2}$ ) must be adjusted according to the selected oscillator.

### 4.3.1.1 HSECLK high-speed external clock signal

HSECLK clock signal is generated by HSECLK external crystal/ceramic resonator and HSECLK external clock two kinds of clock sources.

| Name  | Instruction  |
|---|--|
| External clock source<br>(HSECLK bypass)                  | Provide clock to MCU through OSC_IN pin.<br>The signal can be generated by ordinary function signal transmitter (in debugging), crystal oscillator and other signal generators; the waveform can be square wave, sine wave or triangle wave with 50% duty cycle, and the maximum frequency is up to 25MHz.   |
|   | For hardware connection, it must be connected to OSC_IN pin, ensuring OSC_OUT pin is suspended; for MCU configuration, the user can select this mode by setting HSEBCFG and HSEEN bits in RCM_CTRL.  |
|   | The clock is provided to MCU by the resonator, and the resonator includes crystal resonator and ceramic resonator.<br>The frequency range is 4-16MHz.  |
| External crystal/ceramic<br>resonator<br>(HSECLK crystal) | When needing to connect OSC_IN and OSC_OUT to the resonator, start<br>and close by setting the HSEEN bit in clock control register RCM_CTRL.<br>HSERDYFLG bit in RCM_CTRL is used to indicate whether the high-<br>speed external oscillator is stable. After startup, the clock is not released<br>until this bit is set to "1" by hardware. If interrupt is allowed in RCM_INT<br>(clock interrupt register), corresponding interrupt will be generated. |

### Table 12 Clock Source Generting HSECLK

## 4.3.1.2 LSECLK low-speed external clock signal

LSECLK clock signal is generated by LSECLK external crystal/ceramic resonator and LSECLK external clock two kinds of clock sources.

### Table 13 Clock Source Generting LSECLK

| Name                                     | Instruction  |
|--|--|
| External clock source<br>(LSECLK bypass) | The cock is provided to to MCU through OSC32_IN pin. |

| Name  | Instruction   |
|---|---|
|   | The signal can be generated by ordinary function signal transmitter (in debugging), crystal oscillator and other signal generators; the waveform can be square wave, sine wave or triangle wave with 50% duty cycle, and the signal frequency needs to be 32.768kHz.<br>For hardware connection, it must be connected to OSC32_IN pin, ensuring OSC32_OUT pin is suspended; for MCU configuration, the user can select this mode by setting LSEBCFG and LSEEN bits in RCM_BDCTRL (backup domain control register).  |
| External crystal/ceramic<br>resonator<br>(LSECLK crystal) | The clock is provided to MCU by the resonator, and the resonator includes crystal resonator and ceramic resonator.<br>The frequency is 32.768kHz.<br>OSC32_IN、OSC32_OUT needs to be connected to the oscillator which can be enabled and disabled through LSEEN bit in RCM_BDCTRL.<br>LSERDYFLG in RCM_BDCTRL indicates whether LSECLK crystal oscillator is stable. At startup stage, LSECLK clock signal is not released until this bit is set to "1" by hardware. If it is allowed in the clock interrupt register, an interrupt request can be generated. |

# 4.3.2 Internal Clock Source

The internal clock includes HSICLK (high-speed internal clock signal) and LSICLK (low-speed internal clock signal).

### 4.3.2.1 HSICLK high-speed internal clock signal

HSICLK clock signal is generated by internal 8MHz RC oscillator.

The RC oscillator frequency of different chips is different, and that of the same chip may be different with the change of temperature and voltage; the HSICLK

clock frequency of each chip has been calibrated to 1% (25 °C,V<sub>DD</sub>=V<sub>DDA</sub>=3.3V) by the manufacturer before leaving the factory. When the system is reset, the value calibrated by the manufacturer will be loaded to RCM\_CTRL; in addition, the users can further adjust the frequency by setting HSITRM in RCM\_CTRL according to the application environment (temperature and voltage) of the site.

HSIRDYFLG bit can be used to indicate whether HSICLK RC oscillator is stable. In the clock startup process, HSICLK RC output clock is not released until the HSIRDYFLG bit is set to 1 by hardware. HSICLK RC can be started or closed by HSIEN bit in RCM\_CTRL.

Compared with HSECLK crystal oscillator, RC oscillator can provide system clock without any external device; the start time of RC oscillator is shorter than that of HSECLK crystal oscillator; even after calibration, its clock frequency accuracy is still inferior to that of HSECLK crystal oscillator.

### 4.3.2.2 LSICLK low-speed internal clock signal

### Main characteristics of LSICLK

LSICLK is generated by RC oscillator, within the range of 40kHz (30kHz and 60kHz. The frequency may change along with the change of temperature and voltage. It can keep running in stop and standby mode and provide clock for independent watchdog and automatic wake-up unit.

LSICLK can be started or closed by LSIEN bit in RCM\_CSTS. LSIRDYFLG bit in RCM\_CSTS indicates whether the low-speed internal oscillator is stable. At startup stage, the clock is not released until this bit is set to "1" by hardware. If it

is allowed in RCM\_INT (clock interrupt register), LSICLK interrupt request will be generated.

# 4.3.3 PLL (Phase Locked Loop)

The internal PLL can be used to double the frequency of HSICLK output clock or HSECLK crystal output clock.

HSICLK/2 or HSECLK can be selected as PLL input clock source, and output PLLCLK after PLL frequency multiplication (frequency multiplication factor can be selected). The clock source and multiplication factor should be selected before being activated. Once PLL is activated, the selection cannot be changed.

When PLL is ready and PLL interrupt in RCM\_INT (clock interrupt register) is allowed, PLL can send interrupt request.

# 4.3.4 Clock Tree

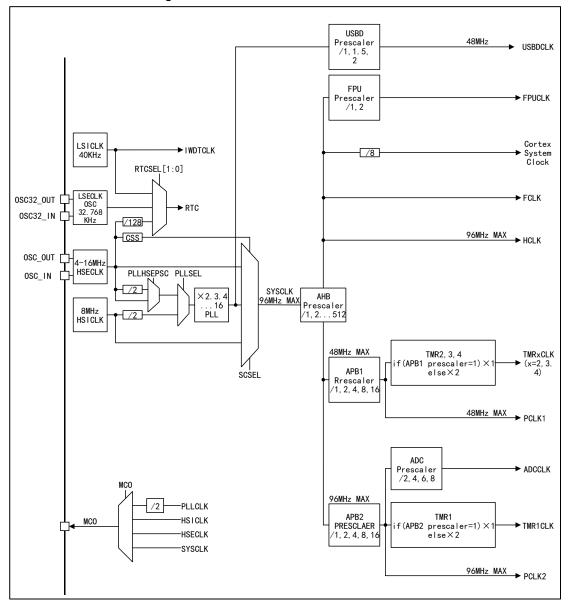

Figure 4 APM32F103x4x6x8xB Clock Tree

Note:

www.geehy.com

- (1) HCLK means AHB clock.
- (2) PCLK1 and PCLK2 are clock signal connected to the peripheral of APB1 and APB2 respectively.
- (3) FCLK is running clock of Arm<sup>®</sup> Cortex<sup>®</sup>-M3.
- (4) The frequency of AHB, APB2 (high-speed APB) and APB1 (low-speed APB) domains can be configured through multiple prescalers. Besides, the maximum frequency of AHB and APB2 domain is 96MHz, while the maximum allowable frequency of APB1 is 48MHz.
- (5) When HSICLK is used as the input of PLL clock, the maximum frequency of the system clock is 64MHz.
- (6) When USBD is used, PLL must be set to output 48/72/96MHz clock, which is used to provide 48MHz USBDCLK clock after the frequency is divided by USBD frequency divider.
- (7) When needing to run the peripheral connected to AHB and APB, it is required to turn on the corresponding enable end to make the peripheral get the clock signal.
- (8) SysTick (system timer) can be provided by the clock signal after frequency division of HCLK8. Different clock sources can be selected by setting SysTick control and status register.
- (9) Frequency assignment of all TMRx\_CLK (timer clocks) is automatically set by the hardware according to the following two situations:
  - If the corresponding APB prescaler factor is 1, the clock frequency of the timer is the same as that of the APB bus.
  - Otherwise, the clock frequency of the timer will be set to twice the frequency of the APB bus connected to it.
- (10) Besides, the frequency of TMRx (x=2,3,4) clock signals is divided by APB1, and the frequency of TMRx (x=1) clock signal is divided by APB2.

## 4.3.5 Clock Source Selection of RTC

HSECLK/128, LSECLK or LSICLK can be selected as RTCCLK clock source by setting RTCSRCSEL bit in RCM\_BDCTRL. The selection of clock source can be changed only when the backup domain is reset.

Because LSECLK is in the backup domain, and HSECLK and LSICLK are not in the backup domain, different clocks will be selected as the RTC clock source; the working condition of clock sources are different, and see the following table for details:

| Clock source              | Working condition  |
|---------------------------|--|
| LSECLK is selected as RTC | As long as $V_{BAT}$ maintains power supply, RTC will continue to work   |
| clock                     | even if V <sub>DD</sub> is powered off   |
| LSICLK is selected as     |  |
| automatic wake-up unit    | If V <sub>DD</sub> is powered off, AWUP state cannot be guaranteed.  |
| (WAKEUP) unit             |  |
| HSECLK/128 as RTC clock   | If the $V_{DD}$ is powered off or the internal voltage regulator is turned off<br>(the power supply of 1.6V domain is cut off), the RTC state is uncertain,<br>so the BPWEN bit (cancel the write protection of backup area) of<br>PMU_CTRL (power control register) must be set to "1". |

Table 14 Working Condition of RTC When RTC Selects Different Clock Sources

# 4.3.6 Clock Source Selection of IWDT

When IWDT (independent watchdog) is opened, LSICLK oscillator will be opened by force, and when it is stable, the clock signal will be provided to IWDT. After LSICLK is opened by force, it will always be open and cannot be closed.

# 4.3.7 Clock Source Selection of MCO

When the corresponding GPIO port register is configured with corresponding function, the clock signal can be selected to be output to MCO pin by MCOSEL in configuration register RCM\_CFG (clock configuration register). See the clock tree or MCOSEL instructions for specific clock signal.

# 4.3.8 Clock Source Selection of SYSCLK

After system reset, HSICLK oscillator is selected as the system clock, which cannot be stopped. If you want to switch the SYSCLK clock source, you must wait until the destination clock source is ready (i.e. the destination clock source is stable). The target clock source can be HSECLK and PLLCLK, and the clock source of PLLCLK can be HSECLK and HSICLK/2.

The state bit of RCM\_CFG can indicate the ready clock and selected SYSCLK clock source.

# 4.3.9 CSS Clock Security System

In order to prevent MCU from normal operation due to external crystal oscillator short circuit, MCU can activate CSS clock security system through software. After the security system is activated, if the HSECLK oscillator is used as the system clock directly or indirectly (used as the PLL input clock and PLL is used as the system clock), the external HSECLK oscillator will be turned off when the HSECLK clock fails, and the system clock will automatically switch to HSICLK. At this time, the PLL which selects HSECLK as the clock input and as the system clock input source will also be turned off.

Note: When CSS is activated by software and HSECLK clock fails, CSS interrupt and NMI (nonmaskable interrupt) will be generated. Since NMI is executed continuously before CSS interrupt is cleared, CSSFLG bit in RCM\_INT register shall be set to clear the interrupt.

# 4.4 Register Address Mapping

| Register name | Description                          | Offset address |
|---------------|--------------------------------------|----------------|
| RCM_CTRL      | Clock control register               | 0x00           |
| RCM_CFG       | Clock configuration register         | 0x04           |
| RCM_INT       | Clock interrupt register             | 0x08           |
| RCM_APB2RST   | APB2 peripheral reset register       | 0x0C           |
| RCM_APB1RST   | APB1 peripheral reset register       | 0x10           |
| RCM_AHBCLKEN  | AHB peripheral clock enable register | 0x14           |
| RCM_APB2CLKEN | APB2 peripheral clock enble register | 0x18           |
| RCM_APB1CLKEN | APB1 peripheral clock enble register | 0x1C           |
| RCM_BDCTRL    | Backup domain control register       | 0x20           |
| RCM_CSTS      | Control/State register               | 0x24           |

### Table 15 RCM Register Address Mapping

# 4.5 Register Functional Description

# 4.5.1 Clock control register (RCM\_CTRL) Offset address: 0x00

Reset value: 0x0000 XX83; X means undefined

Access: Access in the form of word, half word and byte, without wait cycle

| Field | Name      | R/W | Description  |  |  |
|-------|-----------|-----|--|--|--|
| 0     | HSIEN     | R/W | <ul> <li>High Speed Internal Clock Enable</li> <li>Set to 1 or cleared by software.</li> <li>HSICLK is an RC oscillator. When one of the following conditions occurs, it will be set to 1 by the hardware: power-on start, software reset, wake-up from standby mode, wake-up from stop mode, failure of external high-speed clock source (as system clock or providing system clock through PLL). When HSICLK is used as system clock or provides system clock through PLL, this bit cannot be cleared.</li> <li>0: HSICLK RC oscillator is disabled</li> <li>1: HSICLK RC oscillator is turned on</li> </ul> |  |  |
| 1     | HSIRDYFLG | R   | High Speed Internal Clock Ready Flag<br>0: HSICLK RC oscillator is not stable<br>1: HSICLK RC oscillator is stable   |  |  |
| 2     |           |     | Reserved   |  |  |
| 7:3   | HSITRM    | R/W | High Speed Internal Clock Trim<br>The product has been calibrated to 8MHz±1% when leaving the<br>factory. However, it changes as the temperature and voltage<br>changes, but the frequency of HSICLK RC oscillator can be adjusted<br>by HSITRM.   |  |  |
| 15:8  | HSICAL    | R   | High Speed Internal Clock Calibrate<br>It will be calibrated to 8MHz±1% before leaving the factory. When the<br>system is started up, the calibration parameters will be automatically<br>written to the register.   |  |  |
| 16    | HSEEN     | R/W | High Speed External Clock Enable<br>When entering the standby or stop mode, this bit is cleared by<br>hardware and HSECLK is turned off; when HSECLK is used as<br>system clock source or the system clock is provided through PLL,<br>this bit cannot be cleared.<br>0: HSECLK is disabled<br>1: HSECLK is enabled  |  |  |
| 17    | HSERDYFLG | R   | High Speed External Clock Ready Flag<br>When HSECLK is stable, this bit is set to 1 by hardware and cleared<br>by software.<br>0: HSECLK is not stable<br>1: HSECLK is stable  |  |  |
| 18    | HSEBCFG   | R/W | <ul> <li>High Speed External Clock Bypass Configure</li> <li>Bypass mode refers to the mode in which external clock is used as the HSECLK clock source; otherwise the resonator is used as the HSECLK clock source.</li> <li>0: Non-bypass mode</li> <li>1: Bypass mode</li> </ul>   |  |  |
| 19    | CSSEN     | R/W | Clock Security System Enable<br>0: Disable<br>1: Enable, enable the clock detector when HSECLK is stable   |  |  |
| 23:20 | Reserved  |     |  |  |  |
| 24    | PLLEN     | R/W | <ul> <li>PLL Enable</li> <li>When entering the standby or stop mode, this bit is cleared by the hardware; when PLLCLK has been configured (or in the process of configuration) as the clock source of the system clock, this bit cannot be cleared; in other cases, it can be set to 1 or cleared by the software.</li> <li>0: PLL is disabled</li> <li>1: PLL is enabled</li> </ul>   |  |  |

| Field | Name      | R/W | Description   |
|-------|-----------|-----|---|
| 25    | PLLRDYFLG | R   | PLL Clock Ready Flag<br>PLL is set to 1 by hardware after it is locked.<br>0: PLL is unlocked<br>1: PLL is locked |
| 31:26 | Reserved  |     |   |

# 4.5.2 Clock configuration register (RCM\_CFG)

Offset address: 0x04

Reset value: 0x0000 0000

All bits of this register are set or cleared by software.

Access: Access in the form of word, half word and byte, with 0 to two wait cycles.

One or two wait cycles are inserted only when the access occurs during clock switching.

| Field | Name       | R/W | Description  |
|-------|------------|-----|--|
| 1:0   | SYSCLKSEL  | R/W | System Clock Source Select<br>When returning from stop or standby mode or the HSECLK directly<br>or indirectly used as system clock fails, the hardware selects<br>HSICLK as system clock by force (if the clock security system has<br>been started)<br>00: HSICLK is used as system clock<br>01: HSECLK is used as system clock<br>10: PLLCLK is used as system clock<br>11: Reserved  |
| 3:2   | SCLKSELSTS | R   | System Clock Selection Status<br>Indicate which clock source is used as system clock; set to 1 or<br>cleared by the hardware.<br>00: HSICLK is used as system clock<br>01: HSECLK is used as system clock<br>10: PLLCLK is used as system clock<br>11: Reserved  |
| 7:4   | AHBPSC     | R/W | AHB Clock Prescaler Factor Configure<br>0xxx: No frequency division for SYSCLK<br>1000: SYSCLK two-divided frequency<br>1001: SYSCLK four-divided frequency<br>1010: SYSCLK eight-divided frequency<br>1011: SYSCLK 16-divided frequency<br>1100: SYSCLK 64-divided frequency<br>1101: SYSCLK 128-divided frequency<br>1110: SYSCLK 256-divided frequency<br>1111: SYSCLK 512-divided frequency<br>Note: When the prescaler factor of AHB clock is greater than 1,<br>Flash prefetch buffer must be enabled. |

## 4.5.6 AHB peripheral clock enable register (RCM\_AHBCLKEN)

Offset address: 0x14

Reset value: 0x0000 0014

Access: Access in the form of word, half word and byte, without wait cycle All bits can be reset or cleared by software.

Only when the peripheral clock is enabled, can the value of the peripheral register be read; otherwise the value read is 0.

## 4.5.9 Backup domain control register (RCM\_BDCTRL)

Offset address: 0x20

Reset value: 0x0000 0000, which can be reset effectively only by backup domain

Access: Access in the form of word, half word and byte. When the register is accessed continuously, the waiting state will be inserted.

Note: Only when BPWEN bit in PMU\_CTRL is set to 1, can LSEEN, LSEBCFG, RTCSRCSEL and RTCCLKEN be changed.

| Field | Name R/W Description   |  |   |  |  |  |

### 4.5.10 Control/State register (RCM\_CSTS)

Offset address: 0x24 Reset value: 0x0C00 0000

Except reset flag, all are cleared by system reset, and reset flag can only be cleared by power reset.

Access: Access in the form of word, half word and byte. When the register is accessed continuously, the waiting state will be inserted.

# 5 **Power Management Unit (PMU)**

The APM32F103x4x6x8 voltage regulator provides 1.5V power supply and the APM32F103xB voltage regulator provides 1.6V power supply.

## 5.1 Full Name and Abbreviation Description of Terms

| Full name in English   | English abbreviation |
|------------------------|----------------------|
| Power Management Unit  | PMU                  |
| Power On Reset         | POR                  |
| Power Down Reset       | PDR                  |
| Power Voltage Detector | PVD                  |

Table 16 Full Name and Abbreviation Description of Terms

## 5.2 Introduction

The power supply is the basis for stable operation of a system. The working voltage is 2.0~3.6V. It can provide 1.6V power supply through the built-in voltage regulator. If the main power V<sub>DD</sub> is powered down, it can supply power to the backup power supply area through V<sub>BAT</sub>.

## 5.3 Structure Block Diagram

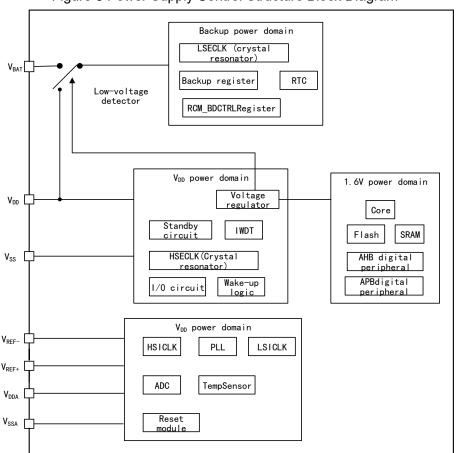

Figure 5 Power Supply Control Structure Block Diagram

## 5.4 Functional Description

### 5.4.1 Power Domain

The power domain of the product includes:  $V_{DD}$  power domain,  $V_{DDA}$  power domain, 1.6V power domain and backup power domain.

### 5.4.1.1 V<sub>DD</sub> power domain

Power supply is provided through  $V_{DD}/V_{SS}$  pins to power the voltage regulator, standby circuit, IWDT, HSECLK, I/O (except PC13, PC14, PC15 pins) and wake-up logic.

### Voltage regulator

Power can be supplied to 1.6V power domain in the following operating modes:

- Normal mode: in this mode, 1.6V power supply area runs at full power
- Stop mode: In this mode, 1.6V power supply area works in low power state, all clocks are off, and peripherals stop working
- Standby mode: In this mode, the 1.6V power supply area stops power supply, and except for the standby circuit, the content of register and SRAM will be lost

### 5.4.1.2 V<sub>DDA</sub> power domain

Power the ADC, HSICLK, LSICLK, TempSensor, PLL and reset module through  $V_{DDA}/V_{SSA}$  and  $V_{REF+}/V_{REF-}$  pins.

### Independent ADC power supply and reference voltage

Independent ADC power supply can improve conversion accuracy, and the specific power pins are as follows:

- V<sub>DDA</sub>: Power pin of ADC
- V<sub>SSA</sub>: Independent power ground pin
- V<sub>REF+</sub>/V<sub>REF-</sub>: ADC reference voltage pin

### 5.4.1.3 1.6V power domain

The core, Flash, SRAM and digital peripherals are powered by voltage regulator.

### 5.4.1.4 Backup power domain

When  $V_{DD}$  exists, the backup power supply area is powered by  $V_{DD}$ . When  $V_{DD}$  is powered down, the backup power supply area is powered by  $V_{BAT}$ , which is used to save the content of backup register and maintain RTC function. Power the LSECLK crystal oscillator, RTC, backup register and RCM\_BDCTRL register, PC13, PC14 and PC15.

### 5.4.2 Power Management

### 5.4.2.1 Power-on/power-down reset (POR and PDR)

When the  $V_{DD}/V_{DDA}$  is detected to be lower than the watermark voltage  $V_{POR}$  and  $V_{PDR}$ , the chip will automatically maintain the reset state. The waveform diagrams of power-on reset and power-down reset are as follows. For POR, PDR, hysteresis voltage and hysteresis time, please refer to the "Datasheet".

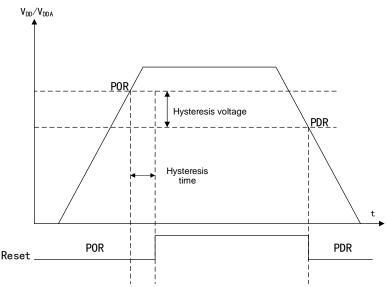

Figure 6 Power-on Reset and Power-down Reset Oscillogram

### 5.4.2.2 Power voltage detector (PVD)

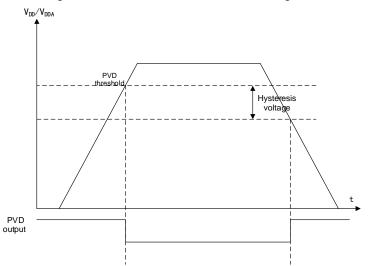

A watermark can be set for PVD to monitor whether  $V_{DD}/V_{DDA}$  is higher or lower than the watermark. If interrupt is enabled, the interrupt can be triggered to

process  $V_{DD}/V_{DDA}$  exceeding the watermark in advance. The usage of PVD is as follows:

- (1) Set the PVDEN bit of the configuration register PMU\_CTRL to 1 to enable PVD
- (2) Select the voltage watermark of PVD for the PLSEL[2:0] bit of the configuration register PMU\_CTRL
- (3) The PVDOFLG bit of the configuration register PMU\_CSTS indicates the value of  $V_{DD}$  is higher or lower than the watermark of PVD
- (4) When it is detected that V<sub>DD</sub>/V<sub>DDA</sub> is lower or higher than the watermark of PVD, PVD interrupt will be generated

The watermark waveform of PVD is shown below. Please see "Datasheet" for PVD watermark and hysteresis voltage.

### 5.4.3 Power Consumption Control

### 5.4.3.1 Reduce the power consumption in low-power mode

There are three low-power modes: sleep mode, stop mode and standby mode. The power consumption is reduced by closing the core and clock source and setting the voltage regulator.

The power consumption, wake-up start time, wake-up mode and data storage of each low-power mode are different; the lower the power consumption is, the longer the wake-up time is, the less the wake-up mode is, the less the data saved are after wake-up; users can choose the most appropriate low-power mode according to their needs. The following table shows the difference among three low-power modes.

| Mode  | Instruction   | Entry mode              | Wake-up mode  | Voltage<br>regulator | Effect on<br>1.6V area<br>clock   | Effect on<br>V <sub>DD</sub> area<br>clock |
|-------|---|-------------------------|---------------|----------------------|---|--|
|       | Arm® Cortex®-<br>M3 core stops,   | Call WFI<br>instruction | Any interrupt | Open                 | Ony the<br>core clock is  | None                                       |
| Sleep | and all<br>peripherals<br>including the<br>core peripheral<br>are still working | Call WFE instruction    | Wake-up event | Open                 | turned off<br>and it has<br>no effect on<br>other clocks<br>and ADC<br>clocks | None                                       |

Table 17 Difference among "Sleep Mode, Stop Mode and Standby Mode"

| Mode    | Instruction             | Entry mode  | Wake-up mode  | Voltage<br>regulator                         | Effect on<br>1.6V area<br>clock | Effect on<br>V <sub>DD</sub> area<br>clock |
|---------|-------------------------|---|---|--|---------------------------------|--|
| Stop    | All clocks have stopped | PDDSCFG and<br>LPDSCFG bits<br>+SLEEPDEEP<br>bit +WFI or<br>WFE | Anny external<br>interrupt  | Turn on<br>or be in<br>low-<br>power<br>mode | Close                           | The<br>oscillator<br>of HSICLK             |
| Standby | 1.6V power off          | PDDSCFG bit<br>+SLEEPDEEP<br>bit +WFI or<br>WFE                 | Rising edge of<br>WKUP pin, RTC<br>alarm clock<br>event, external<br>reset on NRST<br>pin, IWDT reset | Off  | clocks of all<br>1.6V areas     | and<br>HSECLK<br>is turned<br>off          |

## Sleep mode

## The characteristics of sleep mode are shown in the table below

## Table 18 Characteristics of Sleep Mode

| Characteristics | Instruction  |
|-----------------|--|
| Enter           | Enter the sleep mode immediately by executing WFI or WFE instructions;<br>When SLEEPONEINT is set to 0 and WFI or WFE instruction is executed, the<br>system will enter the sleep mode immediately; when SLEEPONEINT is set to 1, the<br>system will exit the interrupt program and then enter the sleep mode immediately. |
| Wake-up         | If WFI instruction is executed to enter the sleep mode, wake up by any interrupt; If WFE instruction is executed to enter the sleep mode, wake up through an event.  |
| Sleep           | The core stops working, all peripherals are still running, and the data in the core registers and memory before sleep are saved.   |
| Wake-up delay   | None   |
| After wake-up   | If the system is woken up by interrupt, it will first enter the interrupt, then exit the interrupt, and then execute the program after WFI instruction. If the system is woken up by event, it will directly execute the program after WFE instruction.  |

### Stop mode

The characteristics of stop mode are shown in the table below:

| Characteristics | Instruction   |
|-----------------|---|
| Enter           | SLEEPDEEP bit of the core register is set to 1, PDDSCFG bit of the register PMU_CTRL is set to 0, and when executing WFI or WFE instruction, the system will enter the stop mode immediately;<br>When LPDSCFG bit of the register PMU_CTRL is set to 0, the voltage regulator is working in normal mode; when LPDSCFG bit of the register PMU_CTRL is set to 1, the voltage regulator is working in low-power mode. |
| Wake-up         | If WFI instruction is executed to enter the sleep mode, wake up by any interrupt; If WFE instruction is executed to enter the sleep mode, wake up through an event.   |
| Stop            | The core will stop working, the peripheral will stop working, and the data in the core register and memory before stop will be saved.   |
| Wake-up delay   | HSICLK oscillator wake-up time + voltage regulator wake-up time from low-power mode.  |
| After wake-up   | If the system is woken up by interrupt, it will first enter the interrupt, then exit the interrupt, and then execute the program after WFI instruction. If the system is woken up by event, it will directly execute the program after WFE instruction.   |

## Standby mode

The characteristics of standby mode are shown in the table below:

| Characteristics | Instruction   |
|-----------------|---|
| Enter           | SLEEPDEEP bit of the core register is set to 1, PDDSCFG bit of the register PMU_CTRL is set to 1, WUEFLG bit is set to 0 and when executing WFI or WFE instruction, the system will enter the standby mode immediately. |
| Wake-up         | Wake up by rising edge of WKUP pin, RTC alarm clock, wake-up, tamper event or NRST pin external reset and IWDT reset.   |
| Standby         | The core will stop working, the peripheral will stop working, and the data in the core register and memory will be lost.  |
| Wake-up delay   | Chip reset time.  |
| After wake-up   | The program starts executing from the beginning.  |

### Table 20 Characteristics of Standby Mode

### 5.4.3.2 Reduce the power consumption in run mode

In the run mode, the power consumption can be reduced by reducing the system clock, closing or reducing the peripheral clock on the APB/AHB bus.

## 5.5 Register Address Mapping

| Table 21 PMU Register Address | s Mapping Table |
|-------------------------------|-----------------|
|-------------------------------|-----------------|

| Register name | Description                  | Offset address |
|---------------|------------------------------|----------------|
| PMU_CTRL      | Power control register       | 0x00           |
| PMU_CSTS      | Power control/state register | 0x04           |

## 5.6 Register Functional Description

# 6 Backup Register (BAKPR)

## 6.1 Introduction

The backup register can be used to store 84 bytes of data, including 42 16-bit registers. When  $V_{DD}$  is closed, the backup domain will be maintained power-on by  $V_{BAT}$ .

Wake up the system in standby mode. If the system is reset or the power supply is reset, the backup register will not be reset. BAKPR control register manages tamper detection and RTC check.

After BAKP is reset, access to the backup register and RTC will be disabled, and the backup domain (BAKPR) will be protected from possible accidental write access. If you want to re-enable the access to the backup register and RTC, operate according to the following steps:

- Enable the power supply and standby interface clock by setting PMU and BAKP bits in RCM APB1CLKEN register
- Enable the access to the backup register and RTC by setting BPWEN bit in PMU\_CTRL power control register

## 6.2 Main Characteristics

- Include 20-byte data register
- The state/control register is used to manage the tamper detection pull-up input with interrupt function
- Check register, which can store RTC calibration value
- Output the RTC calibration clock, RTC alarm clock pulse or second pulse on tamper pin PC13 (TAMPER) (when the pin is not used for tamper detection)

## 6.3 Functional Description

### 6.3.1 Tamper Detection

Judge whether tamper event is generated according to whether the signal on the TAMPER pin changes. Tamper detection event can reset all data backup registers. In order to avoid the loss of tamper events, detect the signal and also detect the edge detection signal and tamper detection enable bit so that the tamper events before detection can be detected. When the TPALCFG bit is set, if the tamper pin is already at a effective level before enabling, an additional tamper event will be generated after the tamper pin is enabled. If TPIEN bit of BAKPR\_CSTS register is also set, an interrupt will be generated when an tamper detection event occurs.

Disable the tamper pin after an tamper event is detected and cleared. If you want to re-enable the tamper detection function, to avoid that there is still tamper detection event on tamper pin when the software writes backup data BAKPR\_DATAx register, it is required to set TPFCFG bit of BAKPR\_CTRL register (equivalent to tamper pin detection) before writing the backup data BAKPR\_DATAx register.

Note: The tamper detection is still active when  $V_{DD}$  is powered off. The tamper pin should be externally connected to the correct level to prevent the reset data backup register from being reset.

## 6.3.2 RTC Calibration

Enable RTC calibration by configuring the CALCOEN bit of RTC clock calibration BAKPR\_CLKCAL register.

RTC clock can be output to the tamper pin through 64 divided frequency.

# 6.4 Register Address Mapping

| Register name       | Description                    | Offset address |
|---------------------|--------------------------------|----------------|
| BAKPR_DATAx(x=110)  | Backup data register x         | 0x04+4(x-1)    |
| BAKPR_CLKCAL        | RTC clock calibration register | 0x2C           |
| BAKPR_CTRL          | Backup control register        | 0x30           |
| BAKPR_CSTS          | Backup control/state register  | 0x34           |
| BAKPR_DATAx(x=1142) | Backup data register x         | 0x40+4(x-1)    |

### Table 22 BAKPR Register Address Mapping

## 6.5 **Register Functional Description**

Peripheral registers can be accessed by half word (16 bits) or word (32 bits).

### 6.5.1 Backup data register x (BAKPR\_DATAx) (x=1...10, 11...42) Offset address: From 0x04 to 0x28, from 0x40 to 0xBC

Reset value: 0x0000 0000

| Field | Name | R/W | Description   |
|-------|------|-----|---|
| 15:0  | DATA | R/W | User Backup Data<br>In the presence of $V_{BAT}$ power supply, BAKPR_DATAx register cannot be<br>reset through power reset, system reset and standby mode wake-up reset,<br>and can only be reset by resetting the backup domain or tamper event. |

## 6.5.2 RTC clock calibration register (BAKPR\_CLKCAL) Offset address: 0x2C

Reset value: 0x0000 0000

| Field | Name     | R/W | Description   |
|-------|----------|-----|---|
| 6:0   | CALVALUE | R/W | Calibration Value Setup<br>Reduce RTC clock by skipping the clock pulse count of RTC, to realize<br>calibration. This value indicates the pulse count of multiple clocks that<br>will be ignored every 2 <sup>20</sup> clock pulses, which can be slowed down from 0<br>to 121ppm.  |
| 7     | CALCOEN  | R/W | Calibration Clock Output Enable<br>0: No output<br>1: For the RTC clock after the tamper pin outputs 64 divided frequency, if<br>LSECLK is 32.768KHz, the output signal frequency is 512Hz. When the<br>CALCOEN bit is set, the tamper detection function needs to be turned off<br>to avoid unnecessary tamper signal detected.<br>Note: This bit will be cleared when V <sub>DD</sub> is powered off. |
| 8     | ASPOEN   | R/W | <ul> <li>Alarm or Second Pulse Output Enable</li> <li>0: Disable</li> <li>1: Output RTC entry alarm or second pulse signal on tamper pin</li> <li>The duration of output pulse is one RTC clock cycle; when setting the</li> <li>ASPOEN bit, the tamper detection function should be disabled.</li> <li>Note: This bit can be clered only by backup domain reset.</li> </ul>                            |

| Field | Name     | R/W Description |  |  |  |
|-------|----------|-----------------|--|--|--|
| 9     | ASPOSEL  | R/W             | Alarm or Second Pulse Output Select<br>This bit can select the tamper pin to output RTC second pulse signal or<br>alarm pulse signal<br>0: Output RTC alarm pulse<br>1: Output RTC second pulse<br>Note: This bit can be clered only by backup domain reset. |  |  |
| 31:10 | Reserved |                 |  |  |  |

## 6.5.3 Backup control register (BAKPR\_CTRL)

Offset address: 0x30 Reset value: 0x0000 0000

| Field | Name   | R/W | Description  |  |  |
|-------|--|-----|--|--|--|
| 0     | TPFCFG   | R/W | TAMPER Pin Function Configure<br>): Tamper pin is used as general-purpose IO port<br>I: Tamper pin is shared in tamper detection |  |  |
| 1     | TPALCFG       R/W       TAMPER Pin Active Level Configure<br>Select the effective level detected by the tamper pin to reset all the<br>data backup registers.         0: High level       1: Low level |     |  |  |  |
| 31:2  | Reserved   |     |  |  |  |

Note: Setting TPALCFG and TPFCFG bits at the same time is always secure. However, a false tamper event will be generated if both are cleared at the same time. Therefore, it is recommended to change the state of TPALCFG bit only when TPFCFG is 0.

## 6.5.4 Backup control/state register (BAKPR\_CSTS)

Offset address: 0x34 Reset value: 0x0000 0000

| Field | Name   | R/W | Description   |  |  |
|-------|--|-----|---|--|--|
| 0     | TECLR  | W   | Tamper Event Flag Clear<br>This bit is write-only, and the read-out value is 0<br>0: Invalid<br>1: Clear the tamper detection event flag and reset the tamper detection |  |  |
|       |  |     | function  |  |  |
| 1     | TICLR  | w   | Tamper Interrupt Flag Clear<br>This bit is write-only, and the read-out value is 0<br>0: Invalid  |  |  |
|       |  |     | 1: Clear the tamper detection interrupt and interrupt flag  |  |  |
| 2     | TAMPER Pin Interrupt Enable         This bit is reset only after system reset or wake-up from standby mode.         TPIEN       R/W         Tamper interrupt cannot wake up the system core in low-power mode.         0: Disable         1: Enable (TPFCFG bit must be set) |     |   |  |  |
| 7:3   | Reserved   |     |   |  |  |

| Field | Name     | R/W | Description  |  |  |
|-------|----------|-----|--|--|--|
| 8     | TEFLG    | R   | <ul> <li>TAMPER Event Occur Flag</li> <li>This bit is set by hardware when an tamper event is detected and it can be cleared by writing 1 to TECLR bit</li> <li>0: No tamper event</li> <li>1: Tamper event detected</li> <li>Note: The tamper event can reset all backup data registers. If the bit is 1, all backup data registers will remain reset, and the backup data cannot be written successfully.</li> </ul> |  |  |
| 9     | TRGIFLG  | R   | TAMPER Interrupt Occur Flag<br>When the TPIEN bit is set and an tamper event is detected, this bit is set<br>by hardware and cleared by writing 1 to the TICLR bit; this bit is reset<br>only after the system is reset or woken up from standby mode.<br>0: No tamper interrupt<br>1: Tamper interrupt occurred   |  |  |

# 7 Nested Vector Interrupt Controller (NVIC)

## 7.1 Full Name and Abbreviation Description of Terms

Table 23 Full Name and Abbreviation Description of Terms

| Full name in English   | English abbreviation |
|------------------------|----------------------|
| Non Maskable Interrupt | NMI                  |

## 7.2 Introduction

The Cortex-M3 core in the product integrates nested vectored interrupt controller (NVIC), which is closely coupled with the core, and can handle exceptions and interrupts and power management control efficiently and with low delay. Please see *Cortex-M3 Technical Reference Manual* for more instructions about NVIC.

## 7.3 Main Characteristics

- 47 maskable interrupt channels (excluding 16 Arm<sup>®</sup> Cortex<sup>®</sup>-M3 interrupt lines)
- 16 programmable priority levels (use 4-bit interrupt priority level)
- Low-delay exception and interrupt processing
- Power management control
- Realization of system control register

# 7.4 Interrupt and Exception Vector Table

|            |   | nterrupt and Exception  |   |

| TMR2                  | 28         | Can be set | 0x0000_00B0    | TMR2 interrupt  |
| TMR3                  | 29         | Can be set | 0x0000_00B4    | TMR3 interrupt  |
| TMR4                  | 30         | Can be set | 0x0000_00B8    | TMR4 interrupt  |
| I2C1_EV               | 31         | Can be set | 0x0000_00BC    | I2C1 event interrupt  |
| I2C1_ER               | 32         | Can be set | 0x0000_00C0    | I2C1 error interrupt  |
| I2C2_EV               | 33         | Can be set | 0x0000_00C4    | I2C2 event interrupt  |
| I2C2_ER               | 34         | Can be set | 0x0000_00C8    | I2C2 error interrupt  |

| Exception type | Vector No. | Priority   | Vector address | Description                     |
|----------------|------------|------------|----------------|---------------------------------|
| SPI1           | 35         | Can be set | 0x0000_00CC    | SPI1 interrupt                  |
| SPI2           | 36         | Can be set | 0x0000_00D0    | SPI2 interrupt                  |
| USART1         | 37         | Can be set | 0x0000_00D4    | USART1 interrupt                |
| USART2         | 38         | Can be set | 0x0000_00D8    | USART2 interrupt                |
| USART3         | 39         | Can be set | 0x0000_00DC    | USART3 interrupt                |
| EINT15_10      | 40         | Can be set | 0x0000_00E0    | EINT line [15:10] interrupt     |
| RTC_Alarm      | 41         | Can be set | 0x0000_00E4    | RTC alarm interrupt             |
| USBD_WakeUP    | 42         | Can be set | 0x0000_00E8    | USBD wake-up interrupt          |
| FPU            | 43         | Can be set | 0x0000_00EC    | FPU interrupt                   |
| QSPI           | 44         | Can be set | 0x0000_00F0    | QSPI interrupt                  |
| USBD2_HP       | 45         | Can be set | 0x0000_00F4    | USB2 high-priority interrupt    |
| USBD2_LP       | 46         | Can be set | 0x0000_00F8    | USBD2 low-priority<br>interrupt |

# 8 External Interrupt and Event Controller (EINT)

## 8.1 Introduction

The interrupts/events contain internal interrupt/event and external interrupt/event. In this manual, external interrupt refers to the interrupt/event caused by I/O pin input signal, which is EINTx in interrupt vector table; other interrupts are internal interrupts/events.

The events can be divided into hardware events and software events. Hardware events are generated by external/core hardware signals, while software events are generated by instructions.

Interrupts need to go through the interrupt handler function to realize the work to be processed, while events do not need to go through interrupt handler function, and the preset work can be triggered by hardware. The external events output pulse through events such as GPIO, while the internal events trigger another TMR to work, for example, through update event of one TMR.

## 8.2 Functional Description

# 8.2.1 "External Interrupt And Event" Classification and Difference Points

"External interrupt and event" can be classified into external hardware interrupt, external hardware event, external software event and external software interrupt according to trigger source, configuration and execution process. The difference points are shown in the table below:

| Name                              | Trigger source                                      | Configuration and execution process   |
|-----------------------------------|---|---|
|                                   |   | (1) Set the trigger mode, allow the interrupt request, and enable corresponding peripheral interrupt line (enable in NVIC);   |
| External<br>hardware<br>interrupt | External signal                                     | (2) When an edge consistent with the configuration is generated<br>on the external interrupt line, an interrupt request will be<br>generated, and the corresponding suspend bit will be set to 1.<br>Write 1 to the corresponding bit of the pending register and the<br>interrupt request will be cleared. |
| External                          |   | (1) Set the trigger mode and enable the event line;   |
| hardware<br>event                 | External signal                                     | (2) When an edge consistent with the configuration is generated<br>on the external interrupt line, one event request pulse will be<br>generated, and the corresponding pending bit will not be set to 1.  |
| External                          | Software interrupt                                  | (1) Enable the event line;  |
| software<br>request               | register/transmission<br>event (SEV)<br>instruction | (2) Write 1 to the software interrupt event register of the corresponding event line to generate an event request pulse, and the corresponding pending bit will not be set to 1.  |
|                                   |   | (1) Allow interrupt request, and enable the corresponding peripheral interrupt line (enable in NVIC);   |
| External<br>software<br>interrupt | Software interrupt<br>register                      | (2) Write 1 to the software interrupt event register of the corresponding event line to generate an interrupt request, the corresponding pending bit will be set to 1; write 1 to the corresponding bit of the pending register and the interrupt request will be cleared.                                  |

### Table 25 "External Interrupt and Event" Classification and Difference Points

### 8.2.2 Core Wake-up

Using WFI and WFE instructions can make the core stop working. When WFI instruction is used, any interrupt can wake up the core; when WFE instruction is used, the core can be waken up by event.

When interrupt is used for wake-up, the interrupt handler function will be triggered, and normal interrupt configuration can wake up the core. When an event is used to wake up the core, the interrupt handler function will not be triggered, which will reduce the wake-up time, and the configuration method is:

- (1) It can trigger an internal interrupt (internal hardware event) but cannot trigger the interrupt handler function for wake-up
  - It can enable an internal interrupt in the peripheral, but cannot enable the corresponding interrupt in NVIC to avoid triggering the interrupt handler function
  - Enable SEVONPEND bit in the system controller of the core, and execute WFE instruction to make the core enter sleep mode
  - Generate an interrupt to wake up the core; when the core recovers from WFE, it is required to clear the pending bit of corresponding peripheral interrupt and the pending bit of peripheral NVIC interrupt channel (clear the pending register in the NVIC interrupt)
- (2) Wake up through EINT line events (external hardware event)
  - Configure EINT line as the event mode
  - Execute WFE instruction to make the core enter the sleep mode
  - Generate an interrupt to wake up the core; when the CPU recovers from WFE, since the pending bit of corresponding event line is not set, it is unnecessary to clear the interrupt pending bit of corresponding peripheral or the NVIC interrupt channel pending bit

### 8.2.2.1 Event wake-up

# It can trigger an internal interrupt (internal hardware event) but cannot trigger the interrupt handler function for wake-up

- (1) Enable an internal interrupt in the peripheral, but do not enable the corresponding interrupt in NVIC to avoid triggering the interrupt handler function;
- (1) Enable SEVONPEND bit in the system controller of the core, and execute WFE instruction to make the core enter sleep mode;
- (2) Generate an interrupt to wake up the core; when the core recovers from WFE, it is required to clear the pending bit of corresponding peripheral interrupt and the pending bit of peripheral NVIC interrupt channel (clear the pending register in the NVIC interrupt).

### Wake up through EINT line events (external hardware event)

- (1) Configure EINT line as the event mode;
- (2) Execute WFE instruction to make the core enter the sleep mode;
- (3) Generate an interrupt to wake up the core; when the CPU recovers from WFE, since the pending bit of corresponding event line is not set, it is unnecessary to clear the interrupt pending bit of corresponding peripheral or the NVIC interrupt channel pending bit.

## 8.2.3 External Interrupt and Event Line Mapping

Table 26 External Interrupt and Event Line Mapping

| External Interrupt and Event Channel Name | External Interrupt and Event Line No. |
|---|---------------------------------------|
| PA0/PB0/PC0/PE0                           | EINT 0                                |
| PA1/PB1/PC1/PE1                           | EINT 1                                |
|   |                                       |
| PA15/PB15/PC15/PE15                       | EINT 15                               |
| PVD output                                | EINT 16                               |
| RTC Alarm event                           | EINT 17                               |
| USBD wake-up event                        | EINT 18                               |
| Reserved                                  | EINT 19                               |
| Reserved                                  | EINT 20                               |
| Reserved                                  | EINT 21                               |
| Reserved                                  | EINT 22                               |
| Reserved                                  | EINT 23                               |
| Reserved                                  | EINT 24                               |
| Reserved                                  | EINT 25                               |
| Reserved                                  | EINT 26                               |
| Reserved                                  | EINT 27                               |
| Reserved                                  | EINT 28                               |
| Reserved                                  | EINT 29                               |
| Reserved                                  | EINT 30                               |
| Reserved                                  | EINT 31                               |

# 8.3 Register Address Mapping

Table 27 External Interrupt/Event Controller Register Mapping

| Register name | Description                                     | Offset address |
|---------------|---|----------------|
| EINT_IMASK    | Interrupt mask register                         | 0x00           |
| EINT_EMASK    | Event mask register                             | 0x04           |
| EINT_RTEN     | Enable the rising edge to trigger the register  | 0x08           |
| EINT_FTEN     | Enable the falling edge to trigger the register | 0x0C           |
| EINT_SWINTE   | Software interrupt event register               | 0x10           |
| EINT_IPEND    | Interrupt pending register                      | 0x14           |

# 8.4 Register Functional Description

### 8.4.1 Interrupt mask register (EINT\_IMASK) Offset address: 0x00 Reset value: 0x0000 0000

| Field | Name   | R/W      | Description  |  |  |
|-------|--------|----------|--|--|--|
| 18:0  | IMASKx | R/W      | Interrupt Request Mask on Line x<br>0: Mask<br>1: Open |  |  |
| 31:19 |        | Reserved |  |  |  |

## 8.4.2 Event mask register (EINT\_EMASK)

Offset address: 0x04 Reset value: 0x0000 0000

| Field | Name       | R/W      | Description                  |  |  |
|-------|------------|----------|------------------------------|--|--|
|       |            |          | Event Request Mask on Line x |  |  |
| 18:0  | EMASKx R/W |          | 0: Mask                      |  |  |
|       |            |          | 1: Open                      |  |  |
| 31:19 |            | Reserved |                              |  |  |

### 8.4.3 Enable the rising edge trigger selection register (EINT\_RTEN) Offset address: 0x08

Reset value: 0x0000 0000

| Field | Name  | R/W  | Description |  |  |
|-------|-------|--|-------------|--|--|
| 18:0  | RTENx | RTENx       R/W       Rising Trigger Event Enable of Line x         0: Disable (interrupt and event)       1: Enable (interrupt and event) |             |  |  |
| 31:19 |       | Reserved   |             |  |  |

Note: Since the external wake-up lines are edge triggered, there should be no burr signal on these lines; when writing EINT\_RTEN register, if the rising edge signal is on the external interrupt line, it will not be recognized and the set pending bit will not be set; in the same interrupt line, the rising edge trigger and falling edge trigger can be set at the same time.

### 8.4.4 Enable the falling edge trigger selection register (EINT\_FTEN) Offset address: 0x0C

Reset value: 0x0000 0000

| Field | Name  | R/W  | Description |  |  |
|-------|-------|--|-------------|--|--|
| 18:0  | FTENx | ENx R/W Falling Trigger Event Enable of Line x<br>1: Enable (interrupt and event)<br>1: Enable (interrupt and event) |             |  |  |
| 31:19 |       | Reserved   |             |  |  |

Note: Since the external wake-up lines are edge triggered, there should be no burr signal on these lines; when writing EINT\_FTEN register, if the rising edge signal is on the external interrupt line, it will not be recognized and the set pending bit will not be set; in the same interrupt line, the rising edge trigger and falling edge trigger can be set at the same time.

## 8.4.5 Software interrupt event register (EINT\_SWINTE)

Offset address: 0x10 Reset value: 0x0000 0000

| Field | Name     | R/W | Description   |  |
|-------|----------|-----|---|--|
| 18:0  | SWINTEX  | R/W | Software Interrupt Event on Line x<br>When this bit is 0, the pending bit of EINT_IPEND can be set by writing 1.<br>If this interrupt is enabled in EINT_IMASK, then an interrupt will be<br>generated.<br>Note: Write 1 in corresponding bit of EINT_IPEND and this bit can be<br>cleared. |  |
| 31:19 | Reserved |     |   |  |

## 8.4.6 Interrupt pending register (EINT\_IPEND)

Offset address: 0x14 Reset value: 0xXXXX XXXX

| Field | Name     | R/W   | Description   |  |  |
|-------|----------|-------|---|--|--|
| 18:0  | IPENDx   | RC_W1 | Interrupt Pending Occur of Line x Flag<br>Whether the selected trigger request occurs<br>0: None<br>1: Occurred<br>This bit will be set when a selective edge trigger request occurs on the<br>external interrupt line. It can be cleared by changing the polarity of<br>edge detection or by writing 1 to the bit. |  |  |
| 31:19 | Reserved |       |   |  |  |

Table 28 Full Name and Abbreviation Description of Terms

## 9.2 Introduction

DMA (Direct Memory Access) can realize high-speed data transmission between peripheral devices and memory or between memory and memory without CPU intervention, thus saving CPU resources for other operations.

The product has a DMA controller, with seven channels. Each channel can manage multiple DMA requests, but each channel can only respond to one DMA request at the same time. Each channel can set priority, and the arbiter can coordinate the priority of corresponding DMA requests of each DMA channel according to the priority of the channels.

## 9.3 Main Characteristics

- (1) DMA has seven channels
- (2) There are three data transmission modes: peripheral to memory, memory to peripheral, memory to memory
- (3) Each channel has a special hardware DMA request for connection
- (4) Support software priority and hardware priority when multiple requests occur at the same time
- (5) Each channel has three event flags and independent interrupts
- (6) Support circular transmission mode

(7) The number of data transmission is programmable, up to 65535

## 9.4 Functional Description

### 9.4.1 DMA Request

If the peripheral or memory needs to use DMA to transmit data, it is required to first send DMA request and wait for DMA approval before data transmission.

DMA has seven channels. Each channel is connected with different peripherals, and each channel has three event flags (DMA half transmission, DMA transmission completion and DMA transmission error). The logic of the three event flags may become a separate interrupt request, and they all support software triggering.

When multiple peripherals request the same channel, it is required to configure the corresponding register to turn on or off the request of each peripheral, so as to ensure that only one peripheral request can be turned on in a channel.

| Peripheral | Channel 1 | Channel 2 | Channel 3           | Channel 4                         | Channel 5 | Channel 6             | Channel 7            |
|------------|-----------|-----------|---------------------|-----------------------------------|-----------|-----------------------|----------------------|
| TMR1       |           | TMR1_CH1  | TMR1_CH2            | TMR1_CH4<br>TMR1_TRIG<br>TMR1_COM | TMR1_UP   | TMR1_CH3              | _                    |
| TMR2       | TMR2_CH3  | TMR2_UP   | _                   | —                                 | TMR2_CH1  | —                     | TMR2_CH2<br>TMR2_CH4 |
| TMR3       |           | TMR3_CH3  | TMR3_CH4<br>TMR3_UP | —                                 | _         | TMR3_CH1<br>TMR3_TRIG | —                    |

| Table 29 DMA Request Mappin |
|-----------------------------|
|-----------------------------|

### 9.4.2 DMA channel

### 9.4.2.1 Transmission data are programmable

The data transmitted by DMA are programmable, up to 65535, and the transmission data bit width of peripherals and memory can be set by configuring PERSIZE bit and MEMSIZE bit of DMA\_CHCFGx register.

### 9.4.2.2 Transmission width and alignment method are programmable

Programmable data transmission width DMA transmission operations:

Figure 8 Transmission Width with Source of 8bits and Target of 8bits

| 0x7 | Data7  |   | Data7  | 0x7 |

### Figure 13 Transmission Width with Source of 16bits and Target of 32bits

### 9.4.2.3 Address setting

The transmission address supports two modes: fixed mode and pointer increment mode.

### Transmission address pointer increment mode

The automatic pointer increment of peripheral and memory is completed through the PERIMODE bit and MIMODE bit of configuration register DMA\_CHCFGx. The next address to be transmitted is the one by adding the increment to the previous address. The increment depends on the selected data width.

### 9.4.2.4 Transmission mode

There are two channel configuration modes: non-circular mode and circular mode.

### Non-circular mode

When the data transmission is finished, the DMA operation will not be performed any more, and the new DMA transmission will be started. When the DMA channel is not working, the register DMA\_CHNDATAx will rewrite the transmission value.

### **Circular mode**

After data transmission, the content of the register DMA\_CHNDATAx will be automatically reloaded to the previously configured value, and the peripheral address register DMA\_CHPADDRx and the memory address register DMA\_CHMADDRx will also be reloaded as the initial base address.

The configuration method is as follows:

- Set the CIRMODE bit of the configuration register DMA\_CHCFGx to 1 to turn on the circular mode;
- This mode is used to process continuous peripheral requests. When the number of data transmission becomes 0, it will automatically return to the initial value and continue DMA operation until the CIRMODE bit is cleared and the system exits the circular mode.

### 9.4.2.5 DMA request priority setting

### Arbitrator

When multiple DMA channel requests occur, an arbiter is needed to manage the response sequence. Management is divided into two stages: the first stage is software stage, which is divided into the highest, high, medium and low priority; the second stage is hardware stage, and under the condition of the same software priority, the lower the channel number is, the higher the priority is.

### 9.4.2.6 Transmission direction

Support three directions: from memory to memory, from memory to peripheral, and from peripheral to memory.

If the write operation (target address) is performed on the memory, the memory includes internal SRAM, external RAM supported by EMMC (such as external SRAM, SDRAM) and NORFLASH; if the read operation (source address) is performed on the memory, the address includes internal FLASH, internal SRAM, RAM supported by EMMC, and NORFLASH.

Examples of "from memory to memory" configuration are as follows:

- The M2MMODE bit of the configuration register DMA\_CHCFGx is set to put the memory to the memory mode;
- The DMA operation in this mode is performed under the condition of no peripheral request. The CHEN bit of the configuration register DMA\_CHCFGx is set to 1, and after the channel is opened, the data transmission will start and when the transmission quantity register DMA\_CHNDATAx becomes 0, the transmission is over.

### 9.4.3 Interrupt

Each DMA channel has three types of interrupt events, which are half transmission (HT), transmission completion (TC) and transmission error (TE).

- (1) The interrupt event flag bit for half transmission is HTFLG, and the interrupt enable control bit is HTINTEN
- (2) The interrupt event flag bit for transmission completion is TCFLG, and the interrupt enable control bit is TCINTEN
- (3) The interrupt event flag bit for transmission error is TERRFLG, and the interrupt enable control bit is TERRINTEN

## 9.5 Register Address Mapping

Table 30 Register Address Mapping

| Register name | Description                                  | Offset address |  |
|---------------|--|----------------|--|

## 10.2 Introduction

APM32F10x MCU series uses Arm<sup>®</sup> Cortex<sup>®</sup>-M3 core, and Arm<sup>®</sup> Cortex<sup>®</sup>-M3 core includes hardware debug module and supports complex debug operation. During debugging, the module can make the running core stop at breakpoint, and achieve the effect of querying the internal state of the core and the external state of the system, and after the query is completed, the core and peripheral operation can be restored to continue to execute the program.

Two debug interfaces are supported:

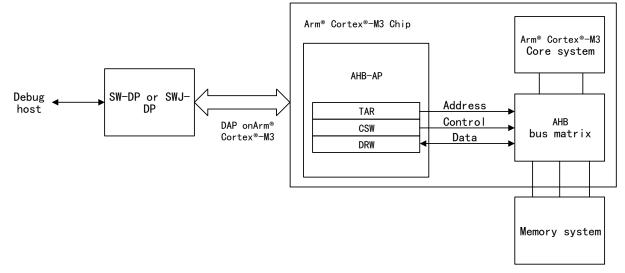

- Serial interface
- JTAG debug interface

Note: The hardware debug interface included in Arm<sup>®</sup> Cortex<sup>®</sup>-M3 core is subset of Arm CoreSight development tool set. Please refer to Cortex<sup>®</sup>-M3 (Version r1p1) technical reference manual (TRM) and CoreSight development tool set (Version r1p0) TRM for more information about debug function of Arm<sup>®</sup> Cortex<sup>®</sup>-M3 core.

## 10.3 Main Characteristics

- (1) Replace the core to access AHB bus matrix
- (2) Flexible debug pin assignment
- (3) MCU debug box (support low-power mode, control peripheral clock, etc.)

Figure 15 APM32F10xxx Level and Arm  $^{\! \mathrm{®}}$  Cortex  $^{\! \mathrm{e}}$  -M3 Level Debugging Block Diagram

# **10.4 Functional Description**

## **10.4.1 Debug Pin Function Configuration**

- (1) Realize the on-line programming and debugging of the chip
- (2) Using KEIL/IAR and other software to achieve on-line debugging, downloading and programming
- (3) Flexible implementation of production of off-line programmer

#### Table 32 Pin Function Configuration

Note: The items that cannot be tested in running mode can be observed and tested in detail

## 10.4.2 ID Code

#### 10.4.2.1 MCU device ID code

APM32F MCU series incudes a MCU ID code. It can be accessed with JTAG or SW debug interface or user code.

#### 10.4.2.2 Boundary scan TAP

#### JTAG ID code

The boundary scan TAP of APM32F MCU series integrates JTAG ID code.

#### 10.4.2.3 Arm<sup>®</sup> Cortex<sup>®</sup>-M3 TAP

Arm<sup>®</sup> Cortex<sup>®</sup>-M3 TAP has a JTAG ID code, which is 0x4BA00477.

### 10.4.2.4 Arm® Cortex®-M3 JEDEC-106 ID code

Arm<sup>®</sup> Cortex<sup>®</sup>-M3 has a JEDEC-106 ID code. It is located in 4KB ROM table in which the internal PPB bus address is 0xE00FF000\_0xE00FFFF.

# 10.5 Register Address Mapping

# **11.2 Main Characteristics**

GPIO port can configure the following functions through 32-bit configuration register (GPIOx\_CFGLOW/GPIOx\_CFGHIG) and two 32-bit data registers GPIOx\_IDATA/GPIOx\_ODATA):

- (1) Input mode
  - Analog input
  - Floating input
  - Pull-up input
  - Pull-down input
- (2) Output mode
  - Push-pull output
  - Open-drain output
  - Configurable maximum output rate
- (3) Multiplexing mode
  - Push-pull multiplexing function
  - Open-drain multiplexing function
- (4) GPIO can be used as external interrupt/wake-up line
- (5) Support locking I/O configuration function

# 11.3 Structure Block Diagram

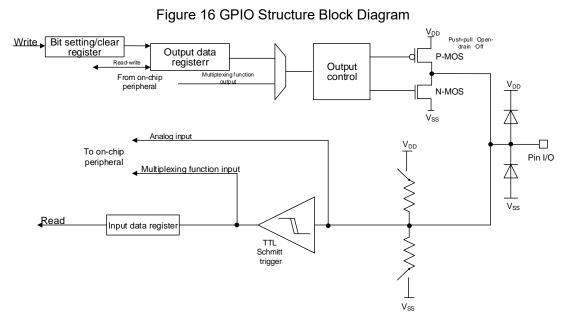

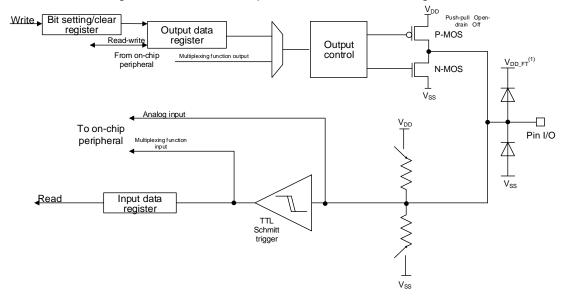

Figure 17 5V GPIO-compatible Structure Block Diagram

(1)  $V_{DD_{FT}}$  is different from  $V_{DD}$ , and  $V_{DD_{FT}}$  is special for FT GPIO pin.

# 11.4 Functional Description

Each pin of GPIO can be configured as pull-up, pull-down, floating and analog input, or push-pull/open-drain output input mode and multiplexing function through software. All GPIO interfaces have external interrupt capability.

## 11.4.1 IO Status during Reset and just after Reset

If the multiplexing function is not enabled during and after GPIO reset, the I/O port will be configured as floating input mode, and in such case the pull-up/pull-down resistor is disabled in input mode. After reset, the JTAG pin is put in the

input pull-up or pull-down mode, and the specific configuration is as follows:

- PA15: JTDI in pull-up mode
- PA14: JTCK in pull-down mode
- PA13: JTMS in pull-up mode
- PB4: JNTRST in pull-up mode

### 11.4.2 Input Mode

In the input mode, it can be set as pull-up, pull-down, floating and analog input.

When GPIO is configured as input mode, all GPIO pins have internal weak pullup and weak pull-down resistors, which can be activated or disconnected.

#### Pull-up, pull-down, and floating modes

In (pull-up, pull-down, floating) input mode

- Schmitt trigger is opened
- Disable output buffer
- Connect weak pull-up and pull-down resistors according to different input configurations
- The input data register GPIOx\_IDATA captures the data on I/O pin in each APB2 clock cycle
- Read I/O state through the input data register GPIOx\_IDATA

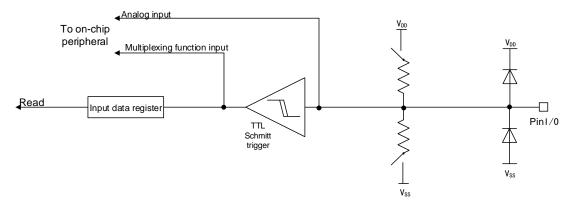

The initial level state of the floating input mode is uncertain and is easy to be disturbed by the outside; when connecting the equipment, it is determined by the external input level (except for the very high impedance).

The initial level state of pull-up/pull-down input mode is high level if pull-up, and low level if pull-down; when connecting the equipment, it is determined by the external input level and load impedance.

#### Analog input mode

In analog input mode

- Disable output buffer
- The input of Schmitt trigger is disabled, and the output value of Schmitt trigger is forced to be 0
- Weak pull-up and pull-down resistors are disabled
- The value of port input state register is 0

#### Figure 18 Input Mode Structure

#### 11.4.3 Output Mode

In the output mode, it can be set as push-pull output and open-drain output.

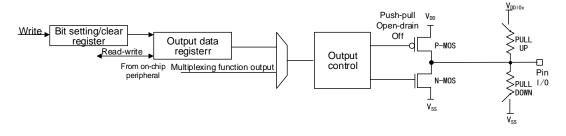

When GPIO is configured as the output pin, the output speed of the port can be configured and the output drive mode (push-pull / open-drain) can be selected.

In output mode

- Schmitt trigger is opened,
- Activate output buffer
- Weak pull-up and pull-down resistors are disabled
- Push-pull mode:
  - Double MOS transistor works by turns and the output data register can control the high and low level of I/O output
  - Read the finally written value through the output data register GPIOx ODATA
- Open-drain mode:
  - Only N-MOS works, and the output data register can control I/O output high resistance state or low level
  - Read the actual I/O state through the input data register GPIOx\_IDATA

Figure 19 I/O Structure in Output Mode

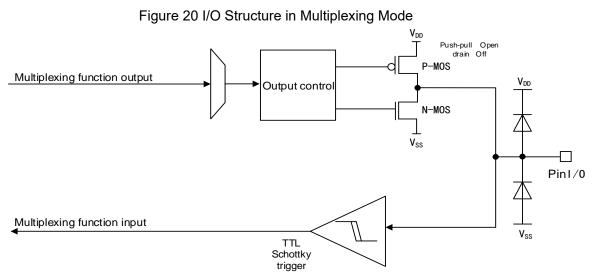

## 11.4.4 Multiplexing Mode

In multiplexing mode, it can be set as push-pull multiplexing and open-drain multiplexing

In push-pull/open-drain multiplexed mode

- Open the output buffer
- Output buffer is driven by peripheral
- Activate schmitt trigger input
- Weak pull-up and pull-down resistors are disabled
- The data on the I/O pin is sampled in each APB2 clock cycle and stored in the port input state register
- In open-drain mode, the actual state of I/O can be read through input data register GPIOx IDATA
- In push-pull mode, the last written value is read through output data register GPIOx ODATA

## 11.4.5 External Interrupt/Wake-up Line

All GPIO ports have external interrupt function. If you want to use external interrupt line, the port must be configured as input mode.

### 11.4.6 Bit Set and Bit Clear

Software does not need to disable interrupt when programming some bits of GPIOx\_IDATA. (The function of changing one or more bits in APB2 write operation can be implemented by setting the bit to be changed in GPIOx\_BSC 和 BSC register to 1.

### 11.4.7 GPIO Locking Function

Locking function can be used in power driver module. The locking mechanism of GPIO can protect the configuration of I/O port. I/O configuration can be locked by configuring the lock register (GPIOx\_LOCK). When a port bit executes the locking program, the configuration of port bit cannot be modified before the next reset.

# 11.5 Register Address Mapping

| Register name | Description                      | Offset address |

| 31:17 | Reserved |     |   |

# 12 Alternate Function Input/Output Pin (AFIO)

# 12.1 Introduction

In addition to the general I/O function, the I/O port can also be used as the interface of various peripheral functions. In order to make full use of the peripheral I/O pins of the product, the product supports the multiplexing function. It can not only realize multiple functions on the same pin (only one function can be realized at the same time), but also remap a certain function to other I/O (the originally supported function is no longer supported).

# 12.2 Functional Description

## 12.2.1 Alternate Function of I/O Pin

In order to make full use of peripheral I/O pins, some multiplexing functions can be remapped to other idle pins to maximize the utilization of pin resources.

| Multiplexing<br>function                  | Configure for port bit configuration register  |
|---|--|
| Multiplexing input<br>function            | Configure as input mode and the input pin must be driven externally  |
| Multiplexing output<br>function           | Configure as multiplexing function output mode   |
| Bidirectional<br>multiplexing<br>function | Configure as multiplexing function output function, and the input driver is configured as floting input mode |

| Table 36 Corres | ponding Port | t Configuratior | n of Multiplexin | g Function |
|-----------------|--------------|-----------------|------------------|------------|
|                 |              |                 |                  |            |

Note:

- (1) Through the GPIO controller programming, use the software to simulate the multiplexing function input pin, then the port is set to the multiplexing function output mode, and the pin is driven by software through the GPIO controller.
- (2) When the multiplexing function is output, the pin is disconnected from the output register and connected with the output signal of the on-chip peripheral. If the peripheral is not activated after connection, the output of the pin will be uncertain.

#### 12.2.1.1 Input mode configuration

When I/O port is used as input mode of multiplexing function, except that the weak pull-up and pull-down resistors are disabled, the port configuration is the same as that of general input function.

See corresponding chapters in GPIO for details of corresponding mode configuration.

#### 12.2.1.2 Output mode configuration

When the I/O port is used as the output mode of multiplexing function (push-pull or open-drain), like the general output function, the output mode can be set as push-pull output and open-drain output, but the output buffer is driven by the signal of the built-in peripheral.

See corresponding chapters in GPIO for details of corresponding mode configuration.

Note: When software simulates multiplexing function input pin, the I/O port should be configured as multiplexing function output mode.

#### 12.2.1.3 Bidirectional multiplexing function configuration

When bidirectional multiplexing function is used, the I/O port must be configured

as multiplexing function output mode (push-pull or open-drain), while the input driver should be configured as floating input mode.

See corresponding chapters in GPIO for details of corresponding mode configuration.

## 12.2.2 Peripheral Pin Configuration

At this time, since the peripheral pin may have different functions, the I/O port configuration of the pin is different.

| TMR pin      | Configure                         | I/O port configuration           |
|--------------|-----------------------------------|----------------------------------|

#### Table 40 I2S Pin Configuration

| I2S pin  | Configure   | I/O port configuration                                |
|----------|-------------|---|
| I2Sx WS  | Master mode | Push-pull multiplexing<br>output                      |
|          | Slave mode  | Floating input  |
| I2Sx CK  | Master mode | Push-pull multiplexing<br>output                      |
|          | Slave mode  | Floating input  |
| 1267 50  | Transmitter | Push-pull multiplexing<br>output                      |
| I2Sx_SD  | Receiver    | Floating input or pull-up<br>input or pull-down input |
| ISSY MCK | Master mode | Push-pull multiplexing<br>output                      |
| I2Sx_MCK | Slave mode  | Unused, can be used as<br>GPIO                        |

## Table 41 I2C Pin Configuration

| I2C pin  | Configure | I/O port configuration            |
|----------|-----------|-----------------------------------|
| I2Cx_SCL | I2C clock | Open-drain multiplexing<br>output |
| I2Cx_SDA | I2C data  | Open-drain multiplexing<br>output |

## Table 42 BxCAN Pin Configuration

| CAN pin | I/O port configuration          |
|---------|---------------------------------|
| CAN_TX  | Push-pull multiplexing output   |
| CAN_RX  | Floating input or pull-up input |

### Table 43 USBD Pin Configuration

|                 | I/O nort configuration                                   |
|-----------------|--|
| USBD pin        | I/O port configuration                                   |
|                 | After the USBD module is enabled, the pin will be        |
| USBD_DM/USBD_DP | automatically connected to the internal USBD transmitter |
|                 | receiver   |

This table is only applicable to small-capacity, medium-capacity and large-capacity products.

#### Table 44 SDIO Pin Configuration

| SDIO pin    | I/O port configuration        |
|-------------|-------------------------------|
| SDIO_CK     | Push-pull multiplexing output |
| SDIO_CMD    | Push-pull multiplexing output |
| SDIO[D7:D0] | Push-pull multiplexing output |

Table 45 ADC/DAC Pin Configuration

| ADC/DAC pin | I/O port configuration |
|-------------|------------------------|
| ADC/DAC     | Analog input           |

## 12.2.3 Remapping Function Configuration

Generally speaking, after the system reset, the pin will be given a default function; then if the user needs to multiplex other functions of the pin, as long as the peripheral is enabled, the multiplexing function can be activated. However, in addition that some peripheral functions need to be enabled, software programming is also needed to map the signal to the port, that is, assign the pin address, so that the peripheral function can be used in the pin.

The multiplexing function and remapping address table of pins are shown in the data manual.

#### 12.2.3.1 OSC32\_IN (OUT) pin is configured as GPIO

When not entering the standby mode or  $V_{DD}$  is not used for power supply, when LSECLK oscillator is closed, the pin OSC32\_IN/OSC32\_OUT can be used as general I/O port PC14/PC15, namely, LSECLK function is prior to general I/O function.

#### 12.2.3.2 OSC\_IN (OUT) pin is configured as GPIO

In package products with less than 100 pins, the user can set AFIO\_REMAP1/2 (multiplexing remapping and debug I/O configuration register) to realize the remapping of general I/O PD0/PD1 to external oscillator pin OSC\_IN/OSC\_OUT. Then PD0 and PD1 cannot be used to generate external interrupt time.

# 12.3 Register Address Mapping

| Register name | Description                                     | Offset<br>address |
|---------------|---|-------------------|
| AFIO_EVCTRL   | Event control register                          | 0x00              |
| AFIO_REMAP1   | Multiplexing remapping configuration register 1 | 0x04              |
| AFIO_EINTSEL1 | External interrupt configuration register 1     | 0x08              |
| AFIO_EINTSEL2 | External interrupt configuration register 2     | 0x0C              |
| AFIO_EINTSEL3 | External interrupt configuration register 3     | 0x10              |
| AFIO_EINTSEL4 | External interrupt configuration register 4     | 0x14              |
| AFIO_REMAP2   | Multiplexing remapping configuration register 2 | 0x18              |

#### Table 46 AFIO Register Address Mapping

# **12.4 Register Functional Description**

For the register AFIO\_EVCTRL, before read and write operation of AFIO\_REMAP1/2 and AFIO\_EINTSELx, AFIO clock shall be opened first. APB2 peripheral cock enable register (RCM\_APB2CLKEN). These peripheral registers must be operated by word (32 bits).

# **12.4.1 Event control register (AFIO\_EVCTRL)** Offset address: 0x00

Reset value: 0x0000 0000

# 13 Timer Overview

## **13.1 Full Name and Abbreviation Description of Terms**

| Full name in English | English abbreviation |
|----------------------|----------------------|
| Timer                | TMR                  |
| Update               | U                    |
| Request              | R                    |
| Event                | EV                   |
| Capture              | С                    |
| Compare              | С                    |
| Length               | LEN                  |

Table 47 Full Name and Abbreviation Description of Terms

# **13.2** Timer Category and Main Difference

In this series of products, there are three types of timers: advanced timer, general-purpose timer and basic timer (watchdog timer and system tick timer are described in other chapters).

The advanced timer includes the functions of general-purpose timer and basic timer. The advanced timer has four capture/comparison channels, supports timing function, input capture and output comparison function, braking and complementary output function, and is a 16-bit timer that can count up/down.

The function of general-purpose timer is simpler than that of advanced timer. The main differences are the total number of channels, the number of complementary output channel groups and the braking function.

The basic timer is a timer that can only realize timing function and has no external interface.

The main differences of timers included in the products are shown in the table below:

| ltem             | Specific<br>content/Category  | Advanced timer               | General-purpose<br>timer     |  |

# 14 Advanced Timer (TMR1)

## 14.1 Introduction

The advanced timer takes the time base unit as the core, and has the functions of input capture, output comparison and braking input, including a 16-bit auto reload counter. Compared with other timers, the advanced timer supports complementary output, repeat count and programmable dead zone insertion function, and is more suitable for motor control.

# 14.2 Main Characteristics

- (1) Timebase unit
  - Counter: 16-bit counter, count-up, count-down and Center-aligned count
  - Prescaler: 16-bit programmable prescaler
  - Repeat counter: 16-bit repeat counter
  - Auto reloading function
- (2) Clock source selection
  - Internal clock
  - External input
  - External trigger
  - Internal trigger
- (3) Input capture function
  - Counting function
  - PWM input mode (measurement of pulse width, frequency and duty cycle)
  - Encoder interface mode
- (4) Output comparison function
  - PWM output mode
  - Forced output mode
  - Single-pulse mode
  - Complementary output and dead zone insertion
- (5) Timing function
- (6) Braking function
- (7) Master/Slave mode controller of timer
  - Timers can be synchronized and cascaded
  - Support multiple slave modes and synchronization signals
- (8) Interrupt output and DMA request event
  - Update event (counter overrun/underrun, counter initialization)
  - Trigger event (counter start, stop, internal/external trigger)
  - Capture/Comparison event
  - Braking signal input event

# 14.3 Structure Block Diagram

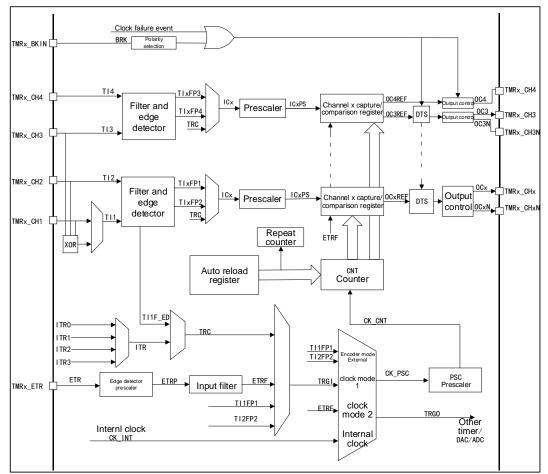

Figure 21 Advanced Timer Structure Block Diagram

# 14.4 Functional Description

## 14.4.1 Clock Source Selection

The advanced timer has four clock sources

#### Internal clock

It is TMRx\_CLK from RCM, namely the driving clock of the timer; when the slave mode controller is disabled, the clock source CK\_PSC of the prescaler is driven by the internal clock CK\_INT.

#### External clock mode 1

The trigger signal generated from the input channel TI1/2/3/4 of the timer after polarity selection and filtering is connected to the slave mode controller to control the work of the counter. Besides, the pulse signal generated by the input of Channel 1 after double-edge detection of the rising edge and the falling edge is logically equal or the future signal is TI1F\_ED signal, namely double-edge signal of TIF\_ED. Specially the PWM input can only be input by TI1/2.

#### External clock mode 2

After polarity selection, frequency division and filtering, the signal from external trigger interface (ETR) is connected to slave mode controller through trigger input selector to control the work of counter.

#### Internal trigger input

The timer is set to work in slave mode, and the clock source is the output signal of other timers. At this time, the clock source has no filtering, and the synchronization or cascading between timers can be realized. The master mode timer can reset, start, stop or provide clock for the slave mode timer.

#### 14.4.2 Timebase Unit

The time base unit in the advanced timer contains four registers

- Counter register (CNT) 16 bits
- Auto reload register (AUTORLD) 16 bits
- Prescaler register (PSC) 16 bits
- Repeat count register (REPCNT) 8 bits

Repeat count register is unique to advanced timer.

#### **Counter CNT**

There are three counting modes for the counter in the advanced timer

- Count-up mode
- Count-down mode
- Center-aligned mode

#### Count-up mode

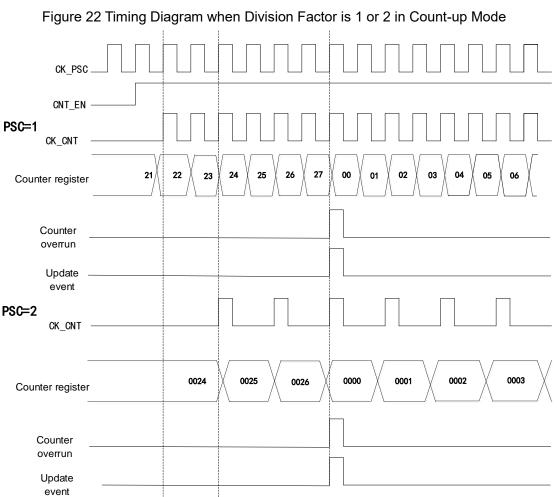

Set to the count-up mode by CNTDIR bit of configuration control register (TMRx\_CTRL1).

When the counter is in count-up mode, the counter will count up from 0; every time a pulse is generated, the counter will increase by 1 and when the value of the counter (TMRx\_CNT) is equal to the value of the auto reload (TMRx\_AUTORLD), the counter will start to count again from 0, a count-up overrun event will be generated, and the value of the auto reload (TMRx\_AUTORLD) is written in advance.

When the counter overruns, an update event will be generated. At this time, the repeat count shadow register, the auto reload shadow register and the prescaler buffer will be updated. The update event can be disabled by UD bit of configuration control register TMRx\_CTRL1.

The figure below is Timing Diagram when Division Factor is 1 or 2 in Count-up Mode

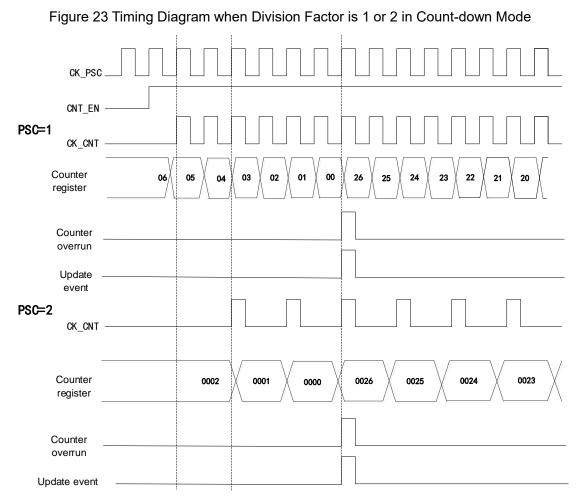

#### Count-down mode

Set to the count-down mode by CNTDIR bit of configuration control register (TMRx\_CTRL1).

When the counter is in count-down mode, the counter will start to count down from the value of the auto reload (TMRx\_AUTORLD); every time a pulse is generated, the counter will decrease by 1 and when it becomes 0, the counter will start to count again from (TMRx\_AUTORLD), meanwhile, a count-down overrun event will be generated, and the value of the auto reload (TMRx\_AUTORLD) is written in advance.

When the counter overruns, an update event will be generated. At this time, the repeat count shadow register, the auto reload shadow register and the prescaler buffer will be updated. The update event can be disabled by configuring the UD bit of the TMRx\_CTRL1 register.

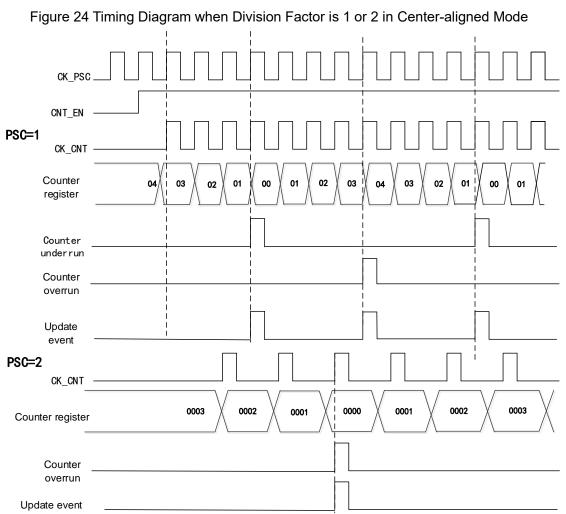

#### Center-aligned mode

Set to the Center-aligned mode by CNTDIR bit of configuration control register (TMRx\_CTRL1).

When the counter is in Center-aligned mode, the counter counts up from 0 to the value of auto reload (TMRx\_AUTORLD), then counts down to 0 from the value of the auto reload (TMRx\_AUTORLD), which will repeat; in counting up, when the counter value is (AUTORLD-1), a counter overrun event will be generated; in counting down, when the counter value is 1, a counter underrun event will be generated.

#### **Repeat counter REPCNT**

There is no repeat counter REPCNT in the basic/general-purpose timer, which means that when the overrun event or underrun event occurs in the basic/general-purpose timer, an update event will be generated directly; while in the advanced timer, because of the existence of the repeat counter, when an overrun/unerrrun event occurs to the advanced timer, the update event will be generated only when the value of the repeat counter is 0.

For example, if the advanced timer needs to generate an update event when an overrun/underrun event occurs, the value of the repeat counter should be set to 0.

If the repeat counter function is used in the count-up mode, every time the counter counts up to AUTORLD, an overrun event will occur. At this time, the value of the repeat counter will be decreased by 1, and an update event will be generated until the value of the repeat counter is 0.

That is, when N+1 (N is the value of repeat counter) overrun/underrun events occur, an update event will be generated.

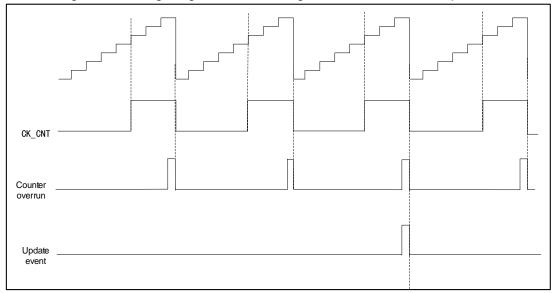

Figure 25 Timing Diagram when Setting REPCNT=2 in Count-up Mode

#### **Prescaler PSC**

The prescaler is 16 bits and programmable, and it can divide the clock frequency of the counter to any value between 1 and 65536 (controlled by TMRx\_PSC register), and after frequency division, the clock will drive the counter CNT to count. The prescaler has a buffer, which can be changed during running.

#### 14.4.3 Input Capture

#### Input capture channel

The advanced timer has four independent capture/comparison channels, each of which is surrounded by a capture/comparison register.

In the input capture, the measured signal will enter from the external pin T1/2/3/4 of the timer, first pass through the edge detector and input filter, and then into the capture channel. Each capture channel has a corresponding capture register. When the capture occurs, the value of the counter CNT will be latched in the capture register CCx. Before entering the capture register, the signal will pass through the prescaler, which is used to set how many events to capture at a time.

#### Input capture application

Input capture is used to capture external events, and can give the time flag to indicate the occurrence time of the event and measure the pulse jump edge events (measure the frequency or pulse width), for example, if the selected edge appears on the input pin, the TMRx\_CCx register will capture the current value of the counter and the CCxIFLG bit of the state register TMRx\_STS will be set to 1; if CCxIEN=1, an interrupt will be generated.

In capture mode, the timing, frequency, cycle and duty cycle of a waveform can be measured. In the input capture mode, the edge selection is set to rising edge detection. When the rising edge appears on the capture channel, the first capture occurs, at this time, the value of the counter CNT will be latched in the capture register CCx; at the same time, it will enter the capture interrupt, a capture will be recorded in the interrupt service program and the value will be

recorded. When the next rising edge is detected, the second capture occurs, the value of counter CNT will be latched in capture register CCx again, at this time, it will enter the capture interrupt again, the value of capture register will be read, and the cycle of this pulse signal will be obtained through capture.

## 14.4.4 Output Comparison

There are eight modes of output comparison: freeze, channel x is valid level when matching, channel x is invalid level when matching, flip, force is invalid, force is valid, PWM1 and PWM2 modes, which are configured by OCxMOD bit in TMRx\_CCMx register and can control the waveform of output signal in output comparison mode.

#### **Output comparison application**

In the output comparison mode, the position, polarity, frequency and time of the pulse generated by the timer can be controlled.

When the value of the counter is equal to that of the capture/comparison register, the channel output can be set as high level, low level or flip by configuring the OCxMOD bit in TMRx\_CCMx register and the CCxPOL bit in the output polarity TMRx\_CCEN register.

When CCxIFLG=1 in TMRx\_STS register, if CCxIEN=1 in TMRx\_DIEN register, an interrupt will be generated; if CCDSEL=1 in TMRx\_CTRL2 register, DMA request will be generated.

#### 14.4.5 PWM Output Mode

PWM mode is an adjustable pulse signal output by the timer. The pulse width of the signal is determined by the value of the comparison register CCx, and the cycle is determined by the value of the auto reload AUTORLD.

PWM output mode contains PWM mode 1 and PWM mode 2; PWM mode 1 and PWM mode 2 are divided into count-up, count-down and edge alignment counting; in PWM mode 1, if the value of the counter CNT is less than the value of the comparison register CCx, the output level will be valid; otherwise, it will be invalid.

Set the timing diagram in PWM1 mode when CCx=5, AUTORLD=7

Figure 26 PWM1 Count-up Mode Timing Diagram

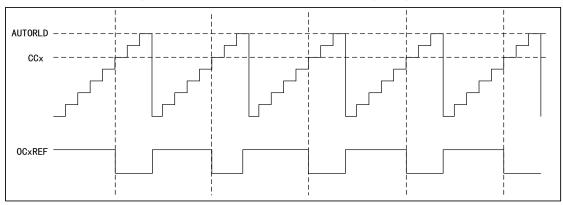

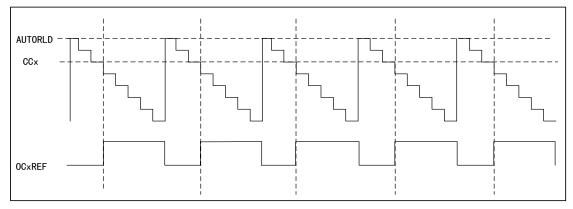

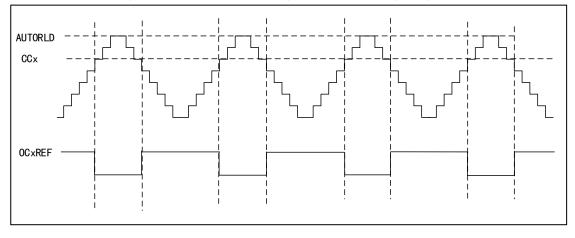

Figure 27 PWM1 Count-down Mode Timing Diagram

## Figure 28 PWM1 Center-aligned Mode Timing Diagram

In PWM mode 2, if the value of the counter CNT is less than that of the comparison register CCx, the output level will be invalid; otherwise, it will be valid.

Set the timing diagram in PWM2 mode when CCx=5, AUTORLD=7

Figure 29 PWM2 Count-up Mode Timing Diagram

Figure 30 PWM2 Count-down Mode Timing Diagram

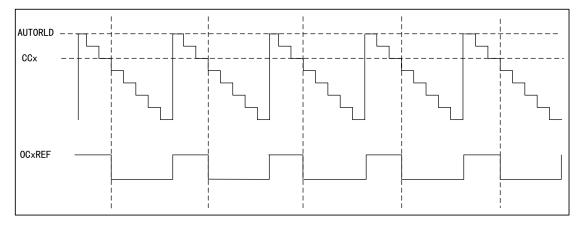

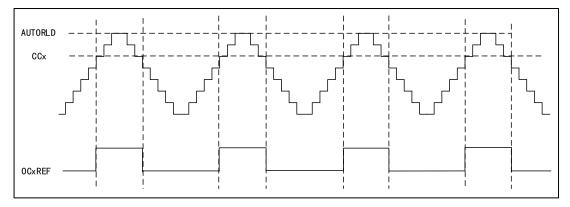

Figure 31 PWM2 Center-aligned Mode Timing Diagram

## 14.4.6 PWM Input Mode

PWM input mode is a particular case of input capture.

In PWM input mode, as only TI1FP1 and TI1FP2 are connected to the slave mode controller, input can be performed only through the channels TMRx\_CH1 and TMRx\_CH2, which need to occupy the capure registers of CH1 and CH2.

In the PWM input mode, the PWM signal enters from TMRx\_CH1, and the signal will be divided into two channels, one can measure the cycle and the other can measure the duty cycle. In the configuration, it is only required to set the polarity of one channel, and the other will be automatically configured with the opposite polarity.

In this mode, the slave mode controller should be configured as the reset mode (SMFSEL bit of TMRx\_SMCTRL register)

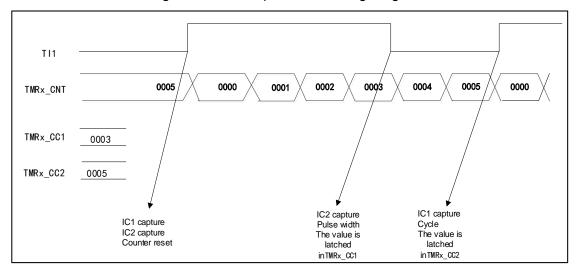

Figure 32 PWM Input Mode Timing Diagram

## 14.4.7 Single-pulse Mode

The single-pulse mode is a special case of timer comparison output, and is also a special case of PWM output mode.

Set SPMEN bit of TMRx\_CTRL1 register, and select the single-pulse mode. After the counter is started, a certain number of pulses will be output before the update event occurs. When an update event occurs, the counter will stop counting, and the subsequent PWM waveform output will no longer be changed.

After a certain controllable delay, a pulse with controllable pulse width is generated in single-pulse mode through the program. The delay time is defined by the value of TMRx\_CCx register; in the count-up mode, the delay time is CCx and the pulse width is AUTORLD-CCx; in the count-down mode, the delay time is AUTORLD-CCx and the pulse width is CCx.

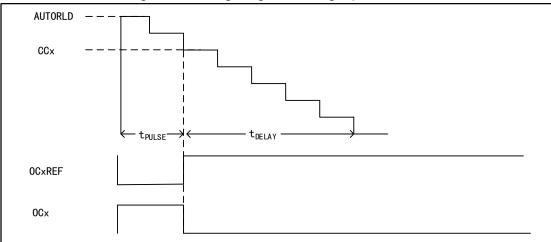

Figure 33 Timing Diagram in Single-pulse Mode

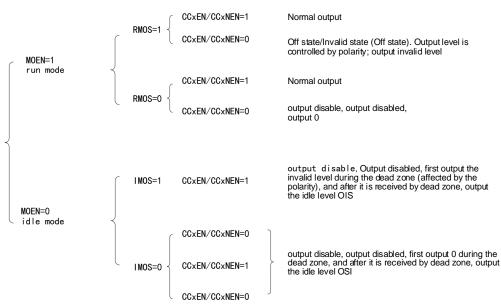

#### 14.4.8 Impact of the Register on Output Waveform

The following registers will affect the level of the timer output waveform. For details, please refer to "Register Functional Description".

- (1) CCxEN and CCxNEN bits in TMRx\_CCEN register
  - CCxNEN=0 and CCxEN=0: The output is turned off (output disabled, invalid state)
  - CCxNEN=1 and CCxEN=1: The output is turned on (output enabled, normal output)
- (2) MOEN bit in TMRx\_BDT register
  - MOEN=0: Idle mode
  - MOEN=1: Run mode
- (3) OCxOIS and OCxNOIS bits in TMRx\_CTRL2 register
  - OCxOIS=0 amd OCxNOIS=0: When idle (MOEN=0), the output level after the dead zone is 0
  - OCxOIS=1 amd OCxNOIS=1: When idle (MOEN=0), the output level after the dead zone is 1
- (4) RMOS bit in TMRx\_BDT register
  - Application environment of RMOS: In corresponding complementary channel and timer are in run mode (MOEN=1), the timer is not working (CCxEN=0, CCxNEN=0) or is working (CCxEN=1, CCxNEN=1)
- (5) IMOS bit in TMRx\_BDT register
  - Application environment of IMOS: In corresponding complementary channel and timer are in idle mode (MOEN=0), the timer is not working (CCxEN=0, CCxNEN=0) or is working (CCxEN=1, CCxNEN=1)
- (6) CCxPOL and CCxNPOL bits of TMRx\_CCEN register
  - CCxPOL=0 and CCxNPOL=0: Output polarity, high level is valid CCxPOL=1 and CCxNPOL=1: Output polarity, the low level is valid

The following figure lists the register structure relationships that affect the output waveform

#### Figure 34 Register Structural Relationship Affecting Output Waveform

## 14.4.9 Braking Function

The signal source of braking is clock fault event and external input interface.

Besides, the BRKEN bit in TMRx\_BDT register can enable the braking function, and the BRKPOL bit can configure the polarity of braking input signal.

When a braking event occurs, the output pulse signal level can be modified according to the state of the relevant control bit.

| OC×REF                            | Brake |  |
|-----------------------------------|-------|--|
| OC×<br>CC×POL=0, OC×01S=0         |       |  |
| 0Cx<br>CCxP0L= <u>0, 0Cx0IS=1</u> |       |  |
| OCx<br>CCxPOL=1, OCx01S=0         |       |  |
| OCx<br>CCXPOL=1, OCx0IS=1         |       |  |

Figure 35 Braking Event Timing Diagram

### 14.4.10 Complementary Output and Dead Zone Insertion

Complementary output is particular output of advanced timer, and the advanced timer has three groups of complementary output channels. The insertion dead time is used to generate complementary output signals to ensure that the two-way complementary signals of channels will not be valid at the same time. The dead time is set according to the output device connected to the timer and its characteristics

The duration of the dead zone can be controlled by configuring DTS bit of TMRx\_BDT register

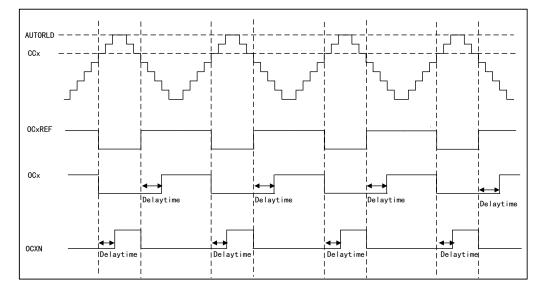

Figure 36 Complementary Output of Insertion with Dead Zone

# 14.4.11 Forced Output Mode

In the forced output mode, the comparison result is ignored, and the corresponding level is directly output according to the configuration instruction.

- CCxSEL=00 for TMRx\_CCMx register, set CCx channel as output
   CCvMOD=100(101 for TMPx, CCMx register, set to force CCvDEE
- OCxMOD=100/101 for TMRx\_CCMx register, set to force OCxREF signal to invalid/valid state

In this mode, the corresponding interrupt and DMA request will still be generated.

### 14.4.12 Encoder Interface Mode

The encoder interface mode is equivalent to an external clock with direction selection. In the encoder interface mode, the content of the timer can always indicate the position of the encoder.

The selection methods of encoder interface is as follows:

- By setting SMFSEL bit of TMRx\_SMCTRL register, set the counter to count on the edge of TI1 channel /TI2 channel, or count on the edge of TI1 and TI2 at the same time.
- Select the polarity of TI1 and TI2 by setting the CC1POL and CC2POL bits of TMRx CCEN register.
- Select to filter or not by setting the IC1F and IC2F bits of TMRx CCM1 register.

The two input TI1 and TI2 can be used as the interface of incremental encoder. The counter is driven by the effective jump of the signals TI1FP1 and TI2FP2 after filtering and edge selection in TI1 and TI2.

The count pulse and direction signal are generated according to the input signals of TI1 and TI2

- The counter will count up/down according to the jumping sequence of the input signal.
- Set CNTDIR of control register TMRx\_CTRL1 to be read-only (CNTDIR will be re-calculated due to jumping of any input end).

The change mechanism of counter count direction is shown in the figure below

|                          | Table 31 Relationship between Count Direction and Encoder |                     |          |                   |               |                              |               |  |

Table 51 Relationship between Count Direction and Encoder

The external incremental encoder can be directly connected with MCU, not needing external interface logic, so the comparator is used to convert the differential output of the encoder to digital signal to increase the immunity from noise interference.

Among the following examples:

- IC1FP1 is mapped to TI1
- IC2FP2 is mapped to TI2
- Neither IC1FP1 nor IC2FP2 is reverse phase
- The input signal is valid at the rising edge and falling edge
- Enable the counter

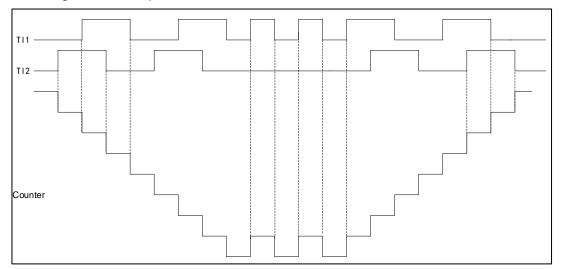

For example, when TI1 is at low level, and TI2 is in rising edge state, the counter will count up.

Figure 38 Example of Encoder Interface Mode of IC1FP1 Reversed Phase

For example, when TI1 is at low level, and the rising edge of TI2 jumps, the counter will count down.

### 14.4.13 Slave Mode

TMRx timer can synchronize external trigger

- Reset mode
- Gated mode
- Trigger mode

SMFSEL bit in TMRx\_SMCTRL register can be set to select the mode.

SMFSEL=100 set the reset mode, SMFSEL=101 set the gated mode, SMFSEL=110 set the trigger mode.

In the reset mode, when a trigger input event occurs, the counter and prescaler will be initialized, and the rising edge of the selected trigger input (TRGI) will reinitialize the counter and generate a signal to update the register.

In the gated mode, the enable of the counter depends on the high level of the selected input. When the trigger input is high, the clock of the counter will be started. Once the trigger input becomes low, the counter will stop (but not be reset). The start and stop of the counter are controlled.

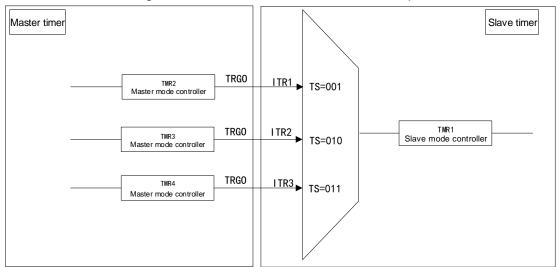

In the trigger mode, the enable of the counter depends on the event on the selected input, the counter is started (but is not reset) at the rising edge of the trigger input, and only the start of the counter is controlled.

### 14.4.14 Timer Interconnection

Each timer of TMRx can be connected with each other to realize synchronization or cascading between timers. It is required to configure one timer in master mode and the other timer in slave mode.

When the timer is in master mode, it can reset, start, stop and provide clock source for the counter of the slave mode timer.

### Figure 39 Timer 1 Master/Slave Mode Example

When the timers are interconnected:

- A timer can be used as the prescaler of other register
- Another register can be started by the enable signal of a timer
- Another register can be started by the update event of a timer
- Another register can be selected by the enable of a timer
- Two timers can be synchronized by an external trigger

### 14.4.15 Interrupt and DMA Request

The timer can generate an interrupt when an event occurs during operation

- Update event (counter overrun/underrun, counter initialization)
- Trigger event (counter start, stop, internal/external trigger)
- Capture/Comparison event
- Braking signal input event

Some internal interrupt events can generate DMA requests, and special interfaces can enable or disable DMA requests.

### 14.4.16 Clear OCxREF Signal when External Events Occur

This function is used for output comparison and PWM mode.

In one channel, the high level of ETRF input port will reduce the signal of OCxREF to low level, and the OCxCEN bit in capture/comparison register TMRx\_CCMx is set to 1, and OCxREF signal will remain low until the next update event.

Set TMRx to PWM mode, close the external trigger prescaler, and disable the external trigger mode 2; when ETRF input is high, set OCxCEN=0, and the output OCxREF signal is shown in the figure below.

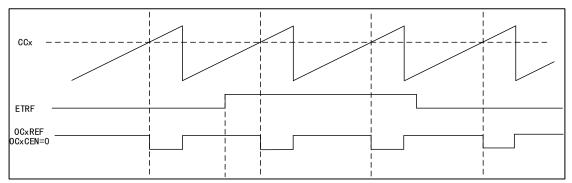

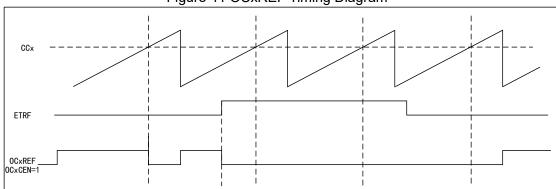

Figure 40 OCxREF Timing Diagram

Set TMRx to PWM mode, close the external trigger prescaler, and disable the external trigger mode 2; when ETRF input is high, set OCxCEN=1, and the output OCxREF signal is shown in the figure below.

# 14.5 Register Address Mapping

In the following table, all registers of the advanced timer are mapped to a 16-bit addressable (address) space.

| Register name | Description                        | Offset<br>address |
|---------------|------------------------------------|-------------------|
| TMRx_CTRL1    | Control register 1                 | 0x00              |
| TMRx_CTRL2    | Control register 2                 | 0x04              |
| TMRx_SMCTRL   | Slave mode control register        | 0x08              |
| TMRx_DIEN     | DMA/Interrupt enable register      | 0x0C              |
| TMRx_STS      | State register                     | 0x10              |
| TMRx_CEG      | Control event generation register  | 0x14              |
| TMRx_CCM1     | Capture/Comparison mode register 1 | 0x18              |
| TMRx_CCM2     | Capture/Comparison mode register 2 | 0x1C              |
| TMRx_CCEN     | Capture/Comparison enable register | 0x20              |
| TMRx_CNT      | Counter register                   | 0x24              |
| TMRx_PSC      | Prescaler register                 | 0x28              |
| TMRx_AUTORLD  | Auto reload register               | 0x2C              |

Table 52 Advanced Timer Register Address Mapping

| Register name | Description                             | Offset<br>address |
|---------------|---|-------------------|
| TMRx_REPCNT   | Repeat count register                   | 0x30              |
| TMRx_CC1      | Channel 1 capture/comparison register   | 0x34              |
| TMRx_CC2      | Channel 2 capture/comparison register   | 0x38              |
| TMRx_CC3      | Channel 3 capure/comparison register    | 0x3C              |
| TMRx_CC4      | Channel 4 capture/comparison register   | 0x40              |
| TMRx_BDT      | Braking and dead zone register          | 0x44              |
| TMRx_DCTRL    | DMA control register                    | 0x48              |
| TMRx_DMADDR   | DMA address register of continuous mode | 0x4C              |

### 14.6.7 Capature/Comparison mode register 1 (TMRx\_CCM1)

Offset address: 0x18

Reset value: 0x0000

The timer can be configured as input (capture mode) or output (comparison mode) by CCxSEL bit. The functions of other bits of the register are different in input and output modes, and the functions of the same bit are different in output mode and input mode. The OCX in the register describes the function of the channel in the output mode, and the ICx in the register describes the function of the channel in the input mode.

|       | Output companison mode. |     |  |  |  |  |
|-------|-------------------------|-----|--|--|--|--|
| Field | Name                    | R/W | Description  |  |  |  |
| 1:0   | CC1SEL                  | R/W | Capture/Compare Channel 1 Selection<br>This bit defines the input/output direction and the selected input pin.<br>00: CC1 channel is output<br>01: CC1 channel is input, and IC1 is mapped on TI1<br>10: CC1 channel is input, and IC1 is mapped on TI2<br>11: CC1 channel is input, and IC1 is mapped on TRC, and only works in<br>internal trigger input |  |  |  |

### Output comparison mode:

| Field | Name   | R/W | Description   |
|-------|--------|-----|---|
|       |        |     | Note: This bit can be written only when the channel is closed (TMRx_CCEN register CC1EN=0).   |
| 2     | OC1FEN | R/W | Output Compare Channel1 Fast Enable<br>0: Disable<br>1: Enable<br>This bit is used to improve the response of the capture/comparison<br>output to the trigger input event.  |
| 3     | OC1PEN | R/W | <ul> <li>Output Compare Channel1 Preload Enable</li> <li>O: Preloading function is disabled; write the value of TMRx_CC1 register through the program and it will work immediately.</li> <li>1: Preloading function is enabled; write the value of TMRx_CC1 register through the program and it will work after an update event is generated.</li> <li>Note: When the protection level is 3 and the channel is configured as output, this bit cannot be modified. When the preload register is uncertain, PWM mode can be used only in single pulse mode (SPMEN=1); otherwise, the following output comparison result is uncertain.</li> </ul>  |
| 6:4   | OC1MOD | R/W | <ul> <li>Output Compare Channel1 Mode Configure</li> <li>000: Freeze The output comparison has no effect on OC1REF</li> <li>001: The output value is high when matching. When the value of counter<br/>CNT matches the value CCx of capture comparison register,<br/>OC1REF will be forced to be at high level</li> <li>010: The output value is low when matching. When the value of the counter<br/>matches the value of the capture comparison register, OC1REF will<br/>be forced to be at low level</li> <li>011: Output flaps when matching. When the value of the counter matches<br/>the value of the capture comparison register, flap the level of<br/>OC1REF</li> <li>100: The output is forced to be ow Force OC1REF to be at low level</li> <li>101: The output is forced to be high. Force OC1REF to be at high level</li> <li>110: PWM mode 1 (set to high when the counter value<output<br>comparison value; otherwise, set to low)</output<br></li> <li>111: PWM mode 2 (set to high when the counter value&gt;output<br/>comparison value; otherwise, set to low)</li> <li>Note: When the protection level is 3 and the channel is configured as<br/>output, this bit cannot be modified. In PWM modes 1 and 2, the OC1REF<br/>level changes when the comparison result changes or when the output<br/>comparison mode changes from freeze mode to PWM mode.</li> </ul> |
| 7     | OC1CEN | R/W | Output Compare Channel1 Clear Enable<br>0: OC1REF is unaffected by ETRF input.<br>1: When high level of ETRF input is detected, OC1REF=0  |

# 15 General-purpose Timer (TMR2/3/4)

# 15.1 Introduction

The general-purpose timer takes the time base unit as the core, and has the functions of input capture and output comparison, and can be used to measure the pulse width, frequency and duty cycle, and generate the output waveform. It includes a 16-bit auto reload counter (realize count-up, count-down and Center-aligned count).

The timer and timer are independent of each other, and they can achieve synchronization and cascading.

# **15.2 Main Characteristics**

- (1) Timebase unit
  - Counter: 16-bit counter, count-up, count-down and Center-aligned count.
  - Prescaler: 16-bit programmable prescaler
  - Auto reloading function
- (2) Clock source selection
  - Internal clock
  - External input
  - External trigger
  - Internal trigger
- (3) Input capture function
  - Counting function
  - PWM input
  - Encoder interface mode
- (4) Output comparison function
  - PWM output mode
  - Forced output mode
  - Single-pulse mode
- (5) Master/Slave mode controller of timer
  - Timers can be synchronized and cascaded
  - Support multiple slave modes and synchronization signals
- (6) Interrupt and DMA request event
  - Update event (counter overrun/underrun, counter initialization)
  - Trigger event (counter start, stop, internal/external trigger)
  - Input capture
  - Output comparison

# 15.3 Structure Block Diagram

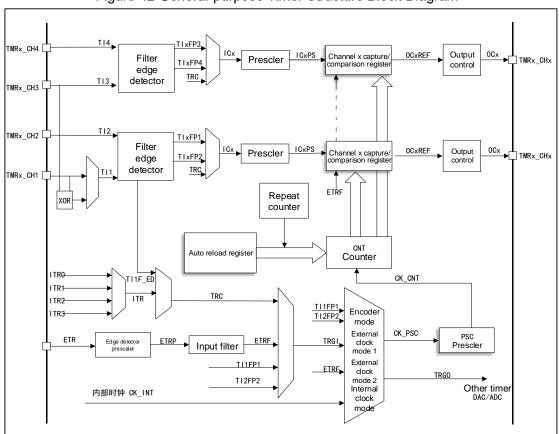

Figure 42 General-purpose Timer Structure Block Diagram

# 15.4 Functional Description

### 15.4.1 Clock Source Selection

The general-purpose timer has four clock sources

### Internal clock

It is TMRx\_CLK from RCM, namely the driving clock of the timer; when the slave mode controller is disabled, the clock source CK\_PSC of the prescaler is driven by the internal clock CK\_INT.

### External clock mode 1

The trigger signal generated from the input channel TI1/2/3/4 of the timer after polarity selection and filtering is connected to the slave mode controller to control the work of the counter. Besides, the pulse signal generated by the input of Channel 1 after double-edge detection of the rising edge and the falling edge is logically equal or the future signal is TI1F\_ED signal, namely double-edge signal of TIF\_ED. Specially the PWM input can only be input by TI1/2.

### External clock mode 2

After polarity selection, frequency division and filtering, the signal from external

trigger interface (ETR) is connected to slave mode controller through trigger input selector to control the work of counter.

#### Internal trigger input

The timer is set to work in slave mode, and the clock source is the output signal of other timers. At this time, the clock source has no filtering, and the synchronization or cascading between timers can be realized. The master mode timer can reset, start, stop or provide clock for the slave mode timer.

### 15.4.2 Timebase Unit

The time base unit in the general-purpose timer contains four registers

- Counter register (CNT) 16 bits
- Auto reload register (AUTORLD) 16 bits
- Prescaler register (PSC) 16 bits

#### **Counter CNT**

There are three counting modes for the counter in the general-purpose timer

- Count-up mode
- Count-down mode
- Center-aligned mode

#### Count-up mode

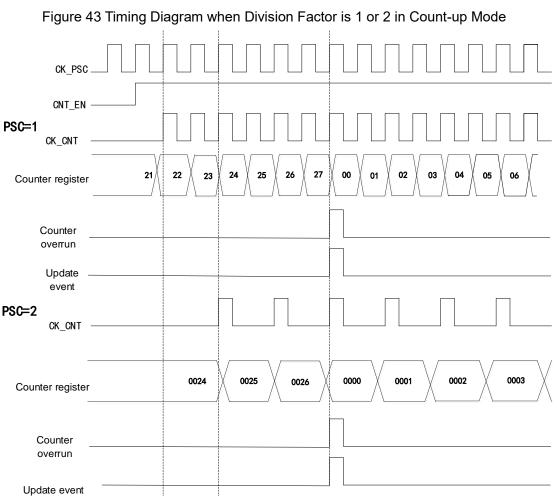

Set to the count-up mode by CNTDIR bit of configuration control register (TMRx\_CTRL1).

When the counter is in count-up mode, the counter will count up from 0; every time a pulse is generated, the counter will increase by 1 and when the value of the counter (TMRx\_CNT) is equal to the value of the auto reload (TMRx\_AUTORLD), the counter will start to count again from 0, a count-up overrun event will be generated, and the value of the auto reload (TMRx\_AUTORLD) is written in advance.

When the counter overruns, an update event will be generated. At this time, the auto reload shadow register and the prescaler buffer will be updated. The update event can be disabled by UD bit of configuration control register TMRx\_CTRL1.

The figure below is Timing Diagram when Division Factor is 1 or 2 in Count-up Mode

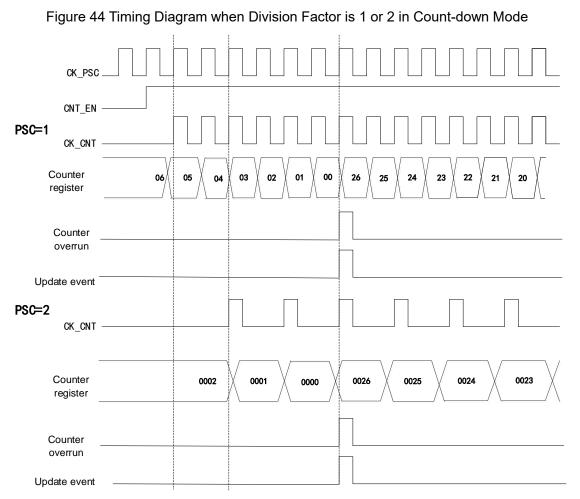

### Count-down mode

Set to the count-down mode by CNTDIR bit of configuration control register (TMRx\_CTRL1).

When the counter is in count-down mode, the counter will start to count down from the value of the auto reload (TMRx\_AUTORLD); every time a pulse is generated, the counter will decrease by 1 and when it becomes 0, the counter will start to count again from (TMRx\_AUTORLD), meanwhile, a count-down overrun event will be generated, and the value of the auto reload (TMRx\_AUTORLD) is written in advance.

When the counter overruns, an update event will be generated. At this time, the auto reload shadow register and the prescaler buffer will be updated. The update event can be disabled by configuring the UD bit of the TMRx\_CTRL1 register.

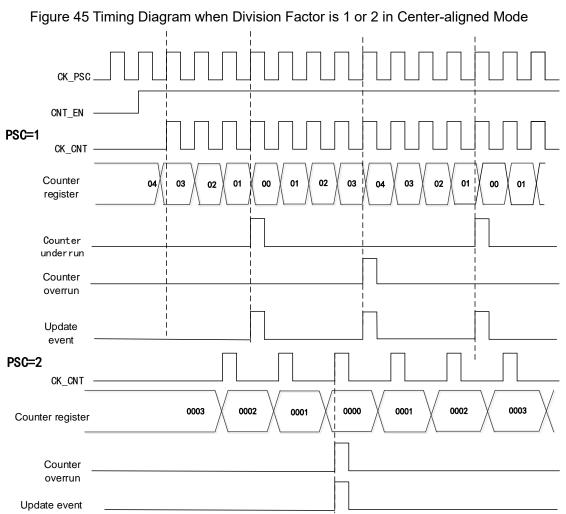

### **Center-aligned mode**

Set to the Center-aligned mode by CNTDIR bit of configuration control register (TMRx\_CTRL1).

When the counter is in Center-aligned mode, the counter counts up from 0 to the value of auto reload (TMRx\_AUTORLD), then counts down to 0 from the value of the auto reload (TMRx\_AUTORLD), which will repeat; in counting up, when the counter value is (AUTORLD-1), a counter overrun event will be generated; in counting down, when the counter value is 1, a counter underrun event will be generated.

#### **Prescaler PSC**

The prescaler is 16 bits and programmable, and it can divide the clock frequency of the counter to any value between 1 and 65536 (controlled by TMRx\_PSC register), and after frequency division, the clock will drive the counter CNT to count. The prescaler has a buffer, which can be changed during running.

### 15.4.3 Input Capture

#### Input capture channel

The general-purpose timer has four independent capture/comparison channels, each of which is surrounded by a capture/comparison register.

In the input capture, the measured signal will enter from the external pin T1/2/3/4 of the timer, first pass through the edge detector and input filter, and then into the capture channel. Each capture channel has a corresponding capture register. When the capture occurs, the value of the counter CNT will be latched in the capture register CCx. Before entering the capture register, the signal will pass through the prescaler, which is used to set how many events to capture at a time.

### Input capture application

Input capture is used to capture external events, and can give the time flag to indicate the occurrence time of the event and measure the pulse jump edge events (measure the frequency or pulse width), for example, if the selected edge appears on the input pin, the TMRx\_CCx register will capture the current value of the counter and the CCxIFLG bit of the state register TMRx\_STS will be set to 1; if CCxIEN=1, an interrupt will be generated.

In capture mode, the timing, frequency, cycle and duty cycle of a waveform can be measured. In the input capture mode, the edge selection is set to rising edge detection. When the rising edge appears on the capture channel, the first capture occurs, at this time, the value of the counter CNT will be latched in the capture register CCx; at the same time, it will enter the capture interrupt, a capture will be recorded in the interrupt service program and the value will be recorded. When the next rising edge is detected, the second capture occurs, the value of counter CNT will be latched in capture register CCx again, at this time, it will enter the capture interrupt again, the value of capture register will be read, and the cycle of this pulse signal will be obtained through capture.

### 15.4.4 Output Comparison

There are eight modes of output comparison: freeze, channel x is valid level when matching, channel x is invalid level when matching, flip, force is invalid, force is valid, PWM1 and PWM2 modes, which are configured by OCxMOD bit in TMRx\_CCMx register and can control the waveform of output signal in output comparison mode.

#### **Output comparison application**

In the output comparison mode, the position, polarity, frequency and time of the pulse generated by the timer can be controlled.

When the value of the counter is equal to that of the capture/comparison register, the channel output can be set as high level, low level or flip by configuring the OCxMOD bit in TMRx\_CCMx register and the CCxPOL bit in the output polarity TMRx\_CCEN register.

When CCxIFLG=1 in TMRx\_STS register, if CCxIEN=1 in TMRx\_DIEN register, an interrupt will be generated; if CCDSEL=1 in TMRx\_CTRL2 register, DMA request will be generated.

### 15.4.5 PWM Output Mode

PWM mode is an adjustable pulse signal output by the timer. The pulse width of the signal is determined by the value of the comparison register CCx, and the cycle is determined by the value of the auto reload AUTORLD.

PWM output mode contains PWM mode 1 and PWM mode 2; PWM mode 1 and PWM mode 2 are divided into count-up, count-down and edge alignment counting; in PWM mode 1, if the value of the counter CNT is less than the value of the comparison register CCx, the output level will be valid; otherwise, it will be invalid.

Set the timing diagram in PWM1 mode when CCx=5, AUTORLD=7

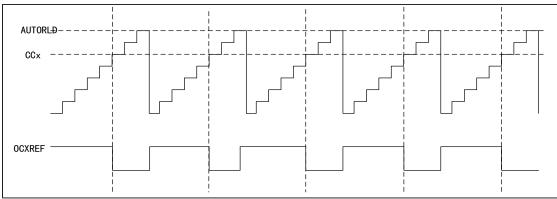

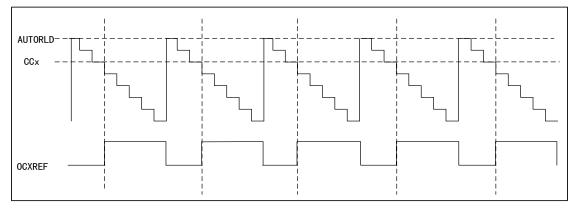

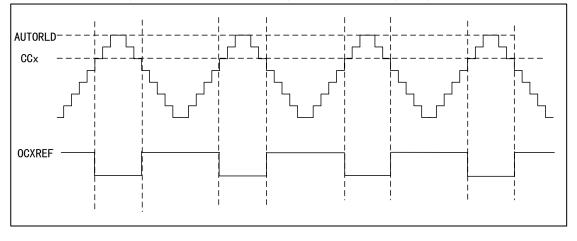

Figure 47 PWM1 Count-down Mode Timing Diagram

# Figure 48 PWM1 Center-aligned Mode Timing Diagram

In PWM mode 2, if the value of the counter CNT is less than that of the comparison register CCx, the output level will be invalid; otherwise, it will be valid.

Set the timing diagram in PWM2 mode when CCx=5, AUTORLD=7

Figure 49 PWM2 Count-up Mode Timing Diagram

Figure 50 PWM2 Count-down Mode Timing Diagram

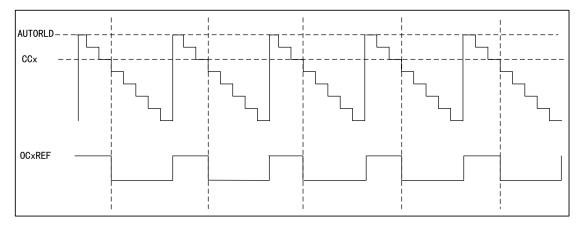

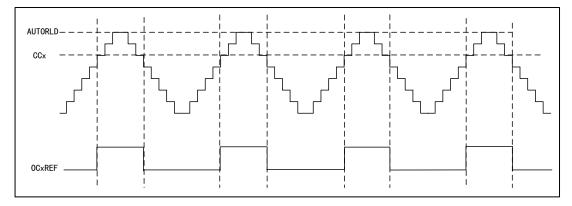

Figure 51 PWM2 Center-aligned Mode Timing Diagram

# 15.4.6 PWM Input Mode

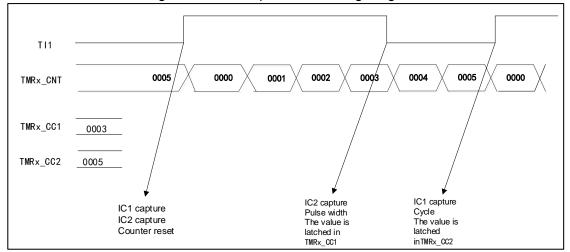

PWM input mode is a particular case of input capture.

In PWM input mode, as only TI1FP1 and TI1FP2 are connected to the slave mode controller, input can be performed only through the channels TMRx\_CH1 and TMRx\_CH2, which need to occupy the capure registers of CH1 and CH2.

In the PWM input mode, the PWM signal enters from TMRx\_CH1, and the signal will be divided into two channels, one can measure the cycle and the other can measure the duty cycle. In the configuration, it is only required to set the polarity of one channel, and the other will be automatically configured with the opposite polarity.

In this mode, the slave mode controller should be configured as the reset mode (SMFSEL bit of TMRx\_SMCTRL register)

### Figure 52 PWM Input Mode Timing Diagram

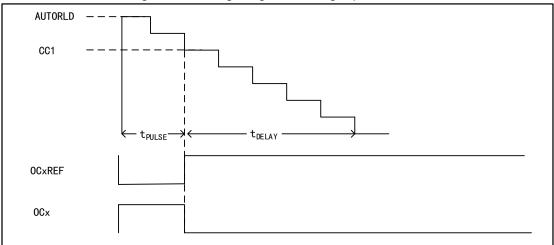

### 15.4.7 Single-pulse Mode

The single-pulse mode is a special case of timer comparison output, and is also a special case of PWM output mode.

Set SPMEN bit of TMRx\_CTRL1 register, and select the single-pulse mode. After the counter is started, a certain number of pulses will be output before the update event occurs. When an update event occurs, the counter will stop counting, and the subsequent PWM waveform output will no longer be changed.

After a certain controllable delay, a pulse with controllable pulse width is generated in single-pulse mode through the program. The delay time is defined by the value of TMRx\_CCx register; in the count-up mode, the delay time is CCx and the pulse width is AUTORLD-CCx; in the count-down mode, the delay time is AUTORLD-CCx and the pulse width is CCx.

#### Figure 53 Timing Diagram in Single-pulse Mode

### 15.4.8 Forced Output Mode

In the forced output mode, the comparison result is ignored, and the corresponding level is directly output according to the configuration instruction.

- CCxSEL=00 for TMRx\_CCMx register, set CCx channel as output
   OCxMOD=100/101 for TMRx\_CCMx register. set to force OCxREF
- OCxMOD=100/101 for TMRx\_CCMx register, set to force OCxREF signal to invalid/valid state

In this mode, the corresponding interrupt and DMA request will still be generated.

### **15.4.9 Encoder Interface Mode**

The encoder interface mode is equivalent to an external clock with direction selection. In the encoder interface mode, the content of the timer can always indicate the position of the encoder.

The selection methods of encoder interface is as follows:

- By setting SMFSEL bit of TMRx\_SMCTRL register, set the counter to count on the edge of TI1 channel /TI2 channel, or count on the edge of TI1 and TI2 at the same time.
- Select the polarity of TI1 and TI2 by setting the CC1POL and CC2POL bits of TMRx\_CCEN register.
- Select to filter or not by setting the IC1F and IC2F bits of TMRx\_CCM1 register.

The two input TI1 and TI2 can be used as the interface of incremental encoder. The counter is driven by the effective jump of the signals TI1FP1 and TI2FP2 after filtering and edge selection in TI1 and TI2. The count pulse and direction signal are generated according to the input signals of TI1 and TI2

- The counter will count up/down according to the jumping sequence of the input signal
- Set CNTDIR of control register TMRx\_CTRL1 to be read-only (CNTDIR will be re-calculated due to jumping of any input end)

The change mechanism of counter count direction is shown in the figure below

| Table 34 Relationship between Count Direction and Encoder |                 |                        |          |                   |               |                              |               |
|---|-----------------|------------------------|----------|-------------------|---------------|------------------------------|---------------|
| Effective edge  |                 | Count only in TI1      |          | Count only in TI2 |               | Count in both TI1<br>and TI2 |               |
| Level of relative signal                                  |                 | High                   | Low      | High              | Low           | High                         | Low           |
| TI1FP1  | Rising<br>edge  |                        |          | Count<br>down     | Count up      | Count<br>down                | Count up      |
|   | Falling<br>edge | _                      | _        | Count up          | Count<br>down | Count up                     | Count<br>down |
| TI2FP2  | Rising<br>edge  | Count up Count<br>down |          |                   |               | Count up                     | Count<br>down |
|   | Falling<br>edge | Count<br>down          | Count up |                   |               | Count<br>down                | Count up      |

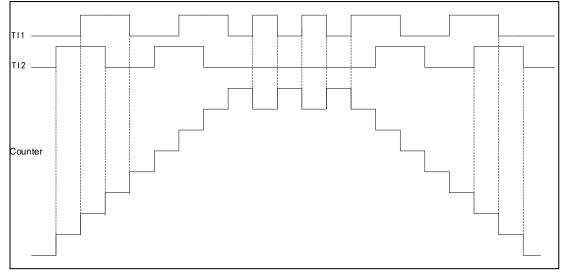

Table 54 Relationship between Count Direction and Encoder

The external incremental encoder can be directly connected with MCU, not needing external interface logic, so the comparator is used to convert the differential output of the encoder to digital signal to increase the immunity from noise interference.

Among the following examples,

- IC1FP1 is mapped to TI1
- IC2FP2 is mapped to TI2
- Neither IC1FP1 nor IC2FP2 is reverse phase
- The input signal is valid at the rising edge and falling edge
- Enable the counter

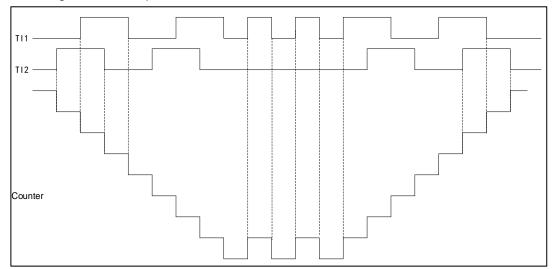

### Figure 54 Counter Operation Example in Encoder Mode

For example, when TI1 is at low level, and TI2 is in rising edge state, the counter will count up.

Figure 55 Example of Encoder Interface Mode of IC1FP1 Reversed Phase

For example, when TI1 is at low level, and the rising edge of TI2 jumps, the counter will count down.

### 15.4.10 Slave Mode

TMRx timer can synchronize external trigger

- Reset mode
- Gated mode
- Trigger mode

SMFSEL bit in TMRx\_SMCTRL register can be set to select the mode

SMFSEL=100 set the reset mode, SMFSEL=101 set the gated mode, SMFSEL=110 set the trigger mode.

In the reset mode, when a trigger input event occurs, the counter and prescaler will be initialized, and the rising edge of the selected trigger input (TRGI) will reinitialize the counter and generate a signal to update the register.

In the gated mode, the enable of the counter depends on the high level of the selected input. When the trigger input is high, the clock of the counter will be started. Once the trigger input becomes low, the counter will stop (but not be reset). The start and stop of the counter are controlled.

In the trigger mode, the enable of the counter depends on the event on the selected input, the counter is started (but is not reset) at the rising edge of the trigger input, and only the start of the counter is controlled.

### 15.4.11 Timer Interconnection

See TMR1 Timer Interconnection for details

### 15.4.12 Interrupt and DMA Request

The timer can generate an interrupt when an event occurs during operation

- Update event (counter overrun/underrun, counter initialization)
- Trigger event (counter start, stop, internal/external trigger)
- Capture/Comparison event

Some internal interrupt events can generate DMA requests, and special interfaces can enable or disable DMA requests.

### 15.4.13 Clear OCxREF Signal when External Events Occur

This function is used for output comparison and PWM mode.

In one channel, the high level of ETRF input port will reduce the signal of OCxREF to low level, and the OCxCEN bit in capture/comparison register TMRx\_CCMx is set to 1, and OCxREF signal will remain low until the next update event.

Set TMRx to PWM mode, close the external trigger prescaler, and disable the external trigger mode 2; when ETRF input is high, set OCxCEN=0, and the output OCxREF signal is shown in the figure below.

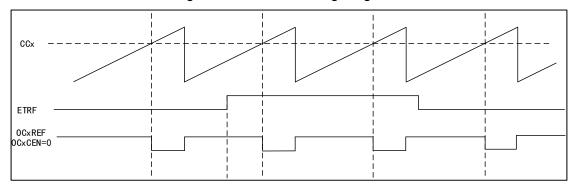

Figure 56 OCxREF Timing Diagram

Set TMRx to PWM mode, close the external trigger prescaler, and disable the external trigger mode 2; when ETRF input is high, set OCxCEN=1, and the output OCxREF signal is shown in the figure below.

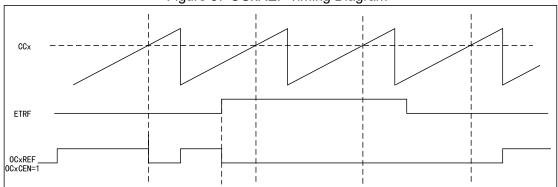

Figure 57 OCxREF Timing Diagram

# 15.5 Register Address Mapping

In the following table, all registers of the general-purpose timer are mapped to a 16-bit addressable (address) space.

| Register name | Description                 | Offset<br>address |
|---------------|-----------------------------|-------------------|
| TMRx_CTRL1    | Control register 1          | 0x00              |

## 15.6 Register Functional Description

## **15.6.1 Control register 1 (TMRx\_CTRL1)** Offset address: 0x00

Reset value: 0x0000

| Field | Name   | R/W | Description  |  |  |
|-------|--------|-----|--|--|--|
| 0     | CNTEN  | R/W | Counter Enable<br>0: Disable<br>1: Enable<br>When the timer is configured as external clock, gated mode and encoder<br>mode, it is required to write 1 to the bit by software to start regular work;<br>when it is configured as the trigger mode, it can be written to 1 by<br>hardware.  |  |  |
| 1     | UD     | R/W | Update Disable<br>Update event can cause AUTORLD, PSC and CCx to generate the value<br>of update setting.<br>0: Update event is allowed (UEV)<br>An update event can occur in any of the following situations:<br>The counter overruns/underruns;<br>Set UEG bit;<br>Update generated by slave mode controller.<br>1: Update event is disabled |  |  |
| 2     | URSSEL | R/W | Update Request Source Select<br>If interrupt or DMA is enabled, the update event can generate update<br>interrupt or DMA request. Different update request sources can be<br>selected through this bit.<br>0: The counter overruns or underruns<br>Set UEG bit<br>Update generated by slave mode controller                                    |  |  |

| Field | Name     | R/W | Description  |  |
|-------|----------|-----|--|--|
|       |          |     | 1: The counter overruns or underruns   |  |
| 3     | SPMEN    | R/W | Single Pulse Mode Enable<br>When an update event is generated, the output level of the channel can<br>be changed; in this mode, the CNTEN bit will be cleared, the counter will<br>be stopped, and the output level of the channel will not be changed.<br>0: Disable<br>1: Enable   |  |
| 4     | CNTDIR   | R/W | Counter Direction.<br>When the counter is configured in central alignment mode or encoder<br>mode, the bit is read-only.<br>0: Count up<br>1: Count down   |  |
| 6:5   | CAMSEL   | R/W | <ul> <li>Center Aligned Mode Select</li> <li>In the Center-aligned mode, the counter counts up and down alternately; otherwise, it will only count up or down. Different Center-aligned modes affect the timing of setting the output comparison interrupt flag bit of the output channel to 1; when the counter is disabled (CNTEN=0), select the Center-aligned mode.</li> <li>00: Edge alignment mode</li> <li>01: Center-aligned mode 1 (the output comparison interrupt flag bit of output channel is set to 1 when counting down)</li> <li>10: Center-aligned mode 2 (the output comparison interrupt flag bit of output channel is set to 1 when counting up)</li> <li>11: Center-aligned mode 3 (the output comparison interrupt flag bit of output channel is set to 1 when counting up)</li> </ul> |  |
| 7     | ARPEN    | R/W | Auto-reload Preload Enable<br>When the buffer is disabled, the program modification TMRx_AUTORLD<br>will immediately modify the values loaded to the counter; when the buffer<br>is enabled, the program modification TMRx_AUTORLD will modify the<br>values loaded to the counter in the next update event.<br>0: Disable<br>1: Enable  |  |
| 9:8   | CLKDIV   | R/W | Clock Divide Factor<br>For the configuration of dead time and digital filter, CK_INT provides the<br>clock, and the dead time and the clock of the digital filter can be adjusted<br>by setting this bit.<br>00: tbts=tck_INT<br>01: tbts=2×tcK_INT<br>10: tbts=4×tcK_INT<br>11: Reserved  |  |
| 15:10 | Reserved |     |  |  |

## **15.6.2 Control register 2 (TMRx\_CTRL2)** Offset address: 0x04

Reset value: 0x0000

| Field | Name     | R/W | Description  |
|-------|----------|-----|--|
| 2:0   | Reserved |     |  |
| 3     | CCDSEL   | R/W | Capture/compare DMA Select<br>0: Send DMA request of CCx when CCx event occurs<br>1: Send DMA request of CCx when an update event occurs |

| Field | Name     | R/W | Description  |  |  |
|-------|----------|-----|--|--|--|
| 6:4   | MMSEL    | R/W | Master Mode Signal Select<br>The signals of timers working in master mode can be used for TRGO,<br>which affects the work of timers in slave mode and cascaded with<br>master timer, and specifically affects the configuration of timers in<br>slave mode.<br>000: Reset; the reset signal of master mode timer is used for TRGO<br>001: Enable; the counter enable signal of master mode timer is used<br>for TRGO<br>010: Update; the update event of master mode timer is used for<br>TRGO<br>011: Comparison pulses; when the master mode timer<br>captures/compares successfully (CCxIFLG=1), a pulse signal is<br>output for TRGO<br>100: Comparison mode 1; OC1REF is used to trigger TRGO<br>101: Comparison mode 2; OC2REF is used to trigger TRGO<br>110: Comparison mode 3; OC3REF is used to trigger TRGO<br>111: Comparison mode 4; OC4REF is used to trigger TRGO |  |  |
| 7     | TI1SEL   | R/W | Timer Input 1 Selection<br>0: TMRx_CH1 pin is connected to TI1 input<br>1: TMRx_CH1, TMRx_CH2 and TMRx_CH3 pins are connected to<br>TI1 input after exclusive  |  |  |

## 15.6.7 Capature/Comparison mode register 1 (TMRx\_CCM1)

Offset address: 0x18

Reset value: 0x0000

The timer can be configured as input (capture mode) or output (comparison mode) by CCxSEL bit. The functions of other bits of the register are different in input and output modes, and the functions of the same bit are different in output mode and input mode. The OCX in the register describes the function of the channel in the output mode, and the ICx in the register describes the function of the channel in the input mode.

| Field | Name   | R/W | Description   |
|-------|--------|-----|---|
| 1:0   | CC1SEL | R/W | Capture/Compare Channel 1 Selection<br>This bit defines the input/output direction and the selected input pin.<br>00: CC1 channel is output<br>01: CC1 channel is input, and IC1 is mapped on TI1<br>10: CC1 channel is input, and IC1 is mapped on TI2<br>11: CC1 channel is input, and IC1 is mapped on TRC, and only works in<br>internal trigger input<br>Note: This bit can be written only when the channel is closed<br>(TMRx_CCEN register CC1EN=0).  |
| 2     | OC1FEN | R/W | Output Compare Channel1 Fast Enable<br>0: Disable<br>1: Enable<br>This bit is used to improve the response of the capture/comparison<br>output to the trigger input event.  |
| 3     | OC1PEN | R/W | <ul> <li>Output Compare Channel1 Preload Enable</li> <li>0: Preloading function is disabled; write the value of TMRx_CC1 register through the program and it will work immediately.</li> <li>1: Preloading function is enabled; write the value of TMRx_CC1 register through the program and it will work after an update event is generated.</li> <li>Note: When the protection level is 3 and the channel is configured as output, this bit cannot be modified. When the preload register is uncertain, PWM mode can be used only in single pulse mode (SPMEN=1); otherwise, the following output comparison result is uncertain.</li> </ul>  |
| 6:4   | OC1MOD | R/W | <ul> <li>Output Compare Channel1 Mode Configure</li> <li>000: Freeze The output comparison has no effect on OC1REF</li> <li>001: The output value is high when matching. When the value of counter CNT matches the value CCx of capture comparison register, OC1REF will be forced to be at high level</li> <li>010: The output value is low when matching. When the value of the counter matches the value of the capture comparison register, OC1REF will be forced to be at low level</li> <li>011: Output flaps when matching. ## 16 Watchdog Timer (WDT)

## 16.1 Introduction

The watchdog is used to monitor system failures caused by software errors. There are two watchdog devices on the chip: independent watchdog and window watchdog, which improve the security, and make the time more accurate and the use more flexible.

The independent watchdog will reset only when the counter is reduced to 0, and the value of refresh counter will not be reset until it is not reduced to 0.

The window watchdog will reset when the counter decreases to 0x3F. When the count value of the counter is before the window value of the configuration register, the refresh counter will also be reset.

## 16.2 Independent Watchdog Timer (IWDT)

## 16.2.1 Introduction

The independent watchdog consists of an 8-bit prescaler IWDT\_PSC, 12-bit count-down counter, 12-bit reload register IWDT\_CNTRLD, key register IWDT\_KEY and state register IWDT\_STS.

The independent watchdog has an independent clock source, and even if the master clock fails, it is still valid.

The independent watchdog is applicable to the situations where an independent environment is required but the accuracy requirement is not high.

## 16.2.2 Structure Block Diagram

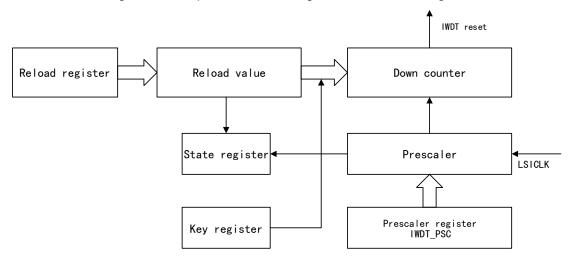

Figure 58 Independent Watchdog Structure Block Diagram

Note: The watchdog function is in the  $V_{DD}$  power supply area and can work normally in the shutdown or standby mode.

## 16.2.3 Functional Description

## 16.2.3.1 Key register

Write 0xCCCC in the key register to enable the independent watchdog, then the counter starts to count down, and when the counter counts to 0x000, a reset will be generated.

Write 0xAAAA in the key register, and the value of the reload register will be reloaded to the counter to prevent the watchdog from resetting.

Write 0x5555 in the key register to rewrite the value of the prescaler register and the reload register.

## 16.2.3.2 Regiser access protection

The prescaler register and reload register have the function of write protection. If you want to rewrite these two registers, you need to write 0X5555 in the key register. If you write other value in the key register, the protection of the register will be started again.

Write 0xAAAA to the key register and the write protection function will also be enabled.

## 16.2.3.3 Hardware watchdog

After the "hardware watchdog" function is enabled, and the system is powered on and reset, the watchdog will run automatically. If 0xAAAA is not written to the key register, reset will be generated after the counter finishes counting.

#### 16.2.3.4 Debug mode

The independent watchdog can be configured in debug mode and choose to stop or continue to work. Depend on IWDT\_STS bit of DBGMCU register.

## 16.3 Window Watchdog Timer (WWDT)

## 16.3.1 Introduction

The window watchdog contains a 7-bit free-running down counter, prescaler and control register WWDT\_CTRL, configuration register WWDT\_CFG and state register WWDT\_STS.

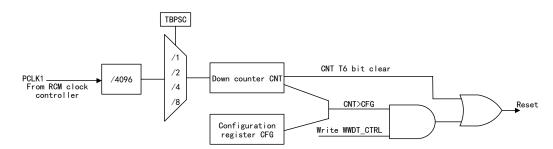

The window watchdog clock comes from PCLK1, and the counter clock is obtained from the CK counter clock through frequency division by prescaler (configured by the configuration register).

The window watchdog is applicable when precise timing is needed.

## 16.3.2 Structure Block Diagram

Figure 59 Window Watchdog Structure Block Diagram

## 16.3.3 Functional Description

Enable window watchdog timer; the reset conditions are:

- When the counter count is less than 0x40, a reset will be generated.
- The reload counter will be reset before the counter counts to the value of the window register.

After reset, the watchdog is always closed and the watchdog can be enabled only by setting the WWDTEN bit of WWDT\_CTRL control register.

The counter of window watchdog is in free state. When the watchdog is disabled, the counter will continue to count down. The counter must be reloaded between the value of window register and 0x40 to avoid reset.

Setting the EWIEN bit of the configuration register can enable the early wake-up interrupt. When the count reaches 0x40, the interrupt will be generated. Entering the interrupt service program (ISTS) can be used to prevent the window watchdog from resetting. EWIEN interrupt can be cleared by writing 0 in the state register.

The unique window of the window watchdog timer can effectively monitor whether the program is faulty. For example, assuming that the running time of a program segment is T, and the value of the window register is slightly less than (TR-T), if there is no reload register in the window, it means that the program is faulty, and when the counter counts to 0x3F, it will generate reset.

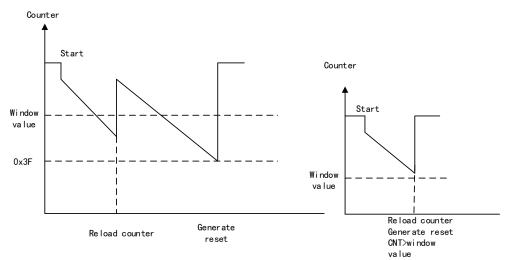

Figure 60 Window Watchdog Timing Diagram

The calculation formula of window watchdog timer timeout is as follows:

## $T_{WWDT} = T_{PCLK1} \times 2^{WTB} \times (T[5:0]+1)$

Wherein:

- T<sub>WWDT</sub>: WWDT timeout
- T<sub>PCLK1</sub>: Clock cycle of APB1 in ms

## Minimum/Maximum timeout when PCLK1=36MHZ

| WTB | Minimum timeout value | Maximum timeout value |
|-----|-----------------------|-----------------------|
| 0   | 113µs                 | 7.28ms                |
| 1   | 227µs                 | 14.56ms               |
| 2   | 455µs                 | 29.12ms               |
| 3   | 910µs                 | 58.25ms               |

## 16.4 IWDT Register Address Mapping

## Table 58 IWDT Register Mapping

| Register name | Description             | Offset address |
|---------------|-------------------------|----------------|
| IWDT_KEY      | Key register            | 0x00           |
| IWDT_PSC      | Prescaler register      | 0x04           |
| IWDT_CNTRLD   | Counter reload register | 0x08           |
| IWDT_STS      | State register          | 0x0C           |

## 16.5 IWDT Register Functional Description

These peripheral registers can be operated by half word (16 bits) or word (32 bits).

## 16.5.1 Key register (IWDT\_KEY)

Offset address: 0x00

Reset value: 0x0000 0000 (reset in standby mode)

| Field | Name     | R/W | Description   |
|-------|----------|-----|---|
| 15:0  | KEY      | w   | Allow Access IWDT Register Key Value<br>Writing 0x5555 means enabled access to IWDT_PSC and IWDT_CNTRLD<br>registers;<br>When the software writes 0xAAAA, it means to execute the reload counter,<br>and a certain interval is required to prevent the watchdog from resetting.<br>Write 0xCCCC and the watchdog will be enabled (the hardware watchdog is<br>unrestricted by this command word);<br>This register is write-only and the read-out vlue is 0x0000. |
| 31:16 | Reserved |     |   |

## 16.5.2 Prescaler register (IWDT\_PSC)

## Offset address: 0x04

Reset value: 0x0000 0000

## 17 Real-time Clock (RTC)

## 17.1 Full Name and Abbreviation Description of Terms

| Full name in English | English abbreviation |
|----------------------|----------------------|
| Second               | SEC                  |
| Alarm                | ALR                  |
| Overflow             | OVR                  |
| Prescaler            | PSC                  |
| Time Basic Clock     | TBCLK                |

Table 60 Full Name and Abbreviation Description of Terms

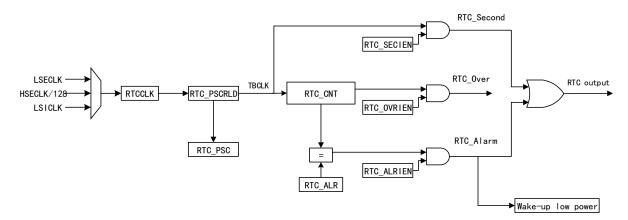

## 17.2 Main Characteristics

Real-time clock (RTC) is a timer that automatically switches to backup power supply after main power failure to maintain the operation.

- Timebase unit
- Programmable 32bit counter
- Multiple interrupt control
- Automatic wakeup of low power

## 17.3 Structure Block Diagram

Figure 61 RTC Structure Block Diagram

## **17.4 Functional Description**

## 17.4.1 Timebase Unit

## **Clock source**

RTC has three clock sources RTC\_CLK:

• External LSECLK crystal oscillator

- External HSECLK crystal oscillator 128 divided frequency
- Internal LSICLK

Different clock sources are configured through RCM peripheral of clock controller.

## Prescaler

The RTC prescaler contains a 20-bit programmable frequency divider, which can be programmed to generate RTC time reference of up to 1 second.

## 17.4.2 RTC Register Configuration

In order to prevent counting exception caused by accidental write in RTC register, RTC adopts write protection mechanism. Only when the write protection is removed, can the register with write protection function be operated.

When configuring RTC clock, it's required to set BPWEN bit of the power control register (PMU\_CTRL) to "1"; configure CFGMFLG bit of RTC\_CSTS register to make the RTC enter the configuration mode so that the RTC\_PSCRLD, RTC\_CNT and RTC\_ALR registers can be configured; clear CFGMFLG bit of RTC\_CSTS register to exit the configuration mode.

The write operation to any register of RTC can be performed only after the previous write operation is finished (judge by querying RTC\_CSTS OCFLG).

## 17.4.3 Programmable Alarm Clock

As a real-time clock, RTC integrates the alarm clock function internally, and it runs mainly through alarm clock register and counter, and configures the alarm clock time through register RTC\_ALR; after the alarm clock function is enabled, when the counter value is equal to the alarm clock value, it will be triggered and the alarm clock flag will be set. If the alarm clock interrupt is enabled, the interrupt processing will be triggered, and through the configuration of external line 17 interrupt, RTC alarm clock can be used to wake up low power consumption.

## 17.4.4 RTC Output

RTC can output the internal RTC second pulse, alarm clock signal and calibration clock to the outside through PC13 pin, and select the output pulse by configuring BAKPR\_CLKCAL register.

## 17.4.5 Interrupt

RTC can generate second interrupt, alarm clock interrupt and overrun interrupt. When 20-bit prescaler overrun, alarm clock event and 32-bit counter overrun are generated, the corresponding state flag bit will be pending and the corresponding interrupt can be generated by configuring RTC CTRL register.

## 17.5 Register Address Mapping

| Register name | Description                               | Offset address |
|---------------|---|----------------|
| RTC_CTRL      | RTC control register                      | 0x00           |
| RTC_CSTS      | RTC control/state register                | 0x04           |
| RTC_PSCRLDH   | High bit of RTC prescaler reload register | 0x08           |

Table 61 RTC Register Address Mapping

| Register name | Description                              | Offset address |
|---------------|--|----------------|
| RTC_PSCRLDL   | Low bit of RTC prescaler reload register | 0x0C           |
| RTC_PSCH      | High bit of RTC prescaler register       | 0x10           |
| RTC_PSCL      | Low bit of RTC prescaler register        | 0x14           |
| RTC_CNTH      | High bit of RTC counter register         | 0x18           |
| RTC_CNTL      | Low bit of RTC counter register          | 0x1C           |
| RTC_ALRH      | High bit of RTC alarm value register     | 0x20           |
| RTC_ALRL      | Low bit of RTC alarm value register      | 0x24           |

#### 17.6 **Register Functional Description**

## 17.6.1 RTC control register (RTC\_CTRL) Offset address: 0x00

| Field | Name     | R/W | Description  |
|-------|----------|-----|--|

| 3     | RSYNCFLG | RC_W0 | Registers Synchronized Flag  |

| Field | Name     | R/W | Description  |
|-------|----------|-----|--|
|       |          |     | When RTC_CNT, RTC_PSCRLD and RTC_ALR registers have been synchronized, it is set to 1 by hardware; it can be cleared by writing 0 by software.   |
|       |          |     | After the APB1 clock is reset or stopped, this bit must be cleared<br>by software, and the user program can correctly read out the<br>values of RTC_CNT, RTC_PSCRLD and RTC_ALR only when it is<br>set to 1 by hardware.<br>0: Not synchronized<br>1: Synchronized   |
| 4     | CFGMFLG  | R/W | Configure Mode Enable Flag<br>Write operation can be performed for RTC_CNT, RTC_ALR or<br>RTC_PSCRLD registers only after writing 1 by software and<br>entering the configuration mode; exit the configuration mode after<br>writing 0 by software.<br>0: Exit configuration mode (start to update RTC register)<br>1: Enable configuration mode |
| 5     | OCFLG    | R   | <ul><li>RTC Operation Complete Flag</li><li>Indicate the state of last write of RTC register.</li><li>0: Uncompleted; next write operation cannot be executed</li><li>1: Completed; next write operation can be executed</li></ul>   |
| 15:6  | Reserved |     |  |

## 17.6.3 RTC prescaler reload register (RTC\_PSCRLD)

This register saves the cycle count value of RTC prescaler, and only when the OCFLG value is 1, can the write operation be performed.

## High bit of RTC prescaler load register (RTC\_PSCRLDH)

## Offset address: 0x08

Reset value: 0x0000

| Field | Name           | R/W | Description  |
|-------|----------------|-----|--|
| 3:0   | PSCRLDH[19:16] | w   | RTC Prescaler Reload Value High Setup<br>These bits can be used to define the frequency of time base clock<br>according to the following formula:<br>$f_{TBCLK}=f_{RTCCLK}/(RLD [19:0]+1)$ |
| 15:4  | Reserved       |     |  |

#### Low bit of RTC prescaler load register (RTC\_PSCRLDL)

Offset address: 0x0C Reset value: 0x8000

| Field | Name          | R/W | Description  |
|-------|---------------|-----|--|
| 15:0  | PSCRLDL[15:0] | W   | RTC Prescaler Reload Value Low Setup<br>These bits can be used to define the frequency of time base clock<br>according to the following formula:<br>$f_{TBCLK}=f_{RTCCLK}/(RLD[19:0]+1)_{\circ}$ |

Note: If the input clock frequency is 32.768kHz (f<sub>RTCCLK</sub>), write 7FFFh in this register to obtain a signal with a cycle of 1 second.

## 17.6.4 RTC prescaer register (RTC\_PSC)

This register saves the value of RTC\_PSCRLD, which is read-only, and can be reloaded by hardware when RTC\_PSCRLD or RTC\_CNT register changes.

## High bit of RTC prescaler register (RTC\_PSCH)

Offset address: 0x10

Reset value: 0x0000

| Field | Name        | R/W | Description                    |
|-------|-------------|-----|--------------------------------|
| 3:0   | PSCH[19:16] | R   | RTC Clock Prescaler High Setup |
| 15:4  | Reserved    |     |                                |

## Low bit of RTC prescaler register (RTC\_PSCL)

Offset address: 0x14

Reset value: 0x8000

| Field | Name       | R/W | Description                   |
|-------|------------|-----|-------------------------------|
| 15:0  | PSCL[15:0] | R   | RTC Clock Prescaler Low Setup |

## 17.6.5 RTC counter register (RTC\_CNT)

When the OCFLG value is 1, write operation is allowed; when read operation is performed, the count value (system time) in the counter will be returned directly.

#### High bit of RTC counter register (RTC\_CNTH)

Offset address: 0x18

Reset value: 0x0000

| Field | Name        | R/W | Description            |  |
|-------|-------------|-----|------------------------|--|
| 15:0  | CNTH[31:16] | R/W | RTC Counter High Setup |  |

#### Low bit of RTC counter register (RTC\_CNTL)

Offset address: 0x1C

Reset value: 0x0000

| Field | Name       | R/W | Description           |  |
|-------|------------|-----|-----------------------|--|
| 15:0  | CNTL[15:0] | R/W | RTC Counter Low Setup |  |

## 17.6.6 RTC alarm clock value register (RTC\_ALR)

Write operation can be performed when OCFLG value is 1.

#### High bit of RTC alarm clock value register (RTC\_ALRH)

#### Offset address: 0x20

Reset value: 0xFFFF

| Field | Name        | R/W | Description                |  |
|-------|-------------|-----|----------------------------|--|
| 15:0  | ALRH[31:16] | W   | RTC Alarm Value High Setup |  |

Low bit of RTC alarm clock value register (RTC\_ALRL)

Offset address: 0x24

Reset value: 0xFFFF

| Field | Name       | R/W | Description               |
|-------|------------|-----|---------------------------|
| 15:0  | ALRL[15:0] | W   | RTC Alarm Value Low Setup |

## 18 Universal Synchronous/Asynchronous Transceiver (USART)

## **18.1 Full Name and Abbreviation Description of Terms**

| Full name in English  | English abbreviation |
|-----------------------|----------------------|
| Clear to Send         | CTS                  |
| Request to Send       | RTS                  |
| Most Significant Bit  | MSB                  |
| Least Significant Bit | LSB                  |
| Guard                 | GRD                  |
| Overrun               | OVR                  |

Table 62 Full Name and Abbreviation Description of Terms

## 18.2 Introduction

USART (universal synchronous/asynchronous transceiver) is a serial communication device that can flexibly exchange full-duplex and half-duplex data with external devices, and meets the requirements of external devices for industry standard NRZ asynchronous serial data format. USART also provides a wide range of baud rate for selection and supports multiprocessor communication.

USART not only supports standard asynchronous transceiver mode, but also supports some other serial data exchange modes, such as LIN protocol, smart card protocol, IrDA SIR ENDEC specification and hardware flow control mode.

USART also supports DMA function to realize high-speed data communication.

## **18.3 Main Characteristics**

- (1) Full duplex asynchronous communication
- (2) Single-line half-duplex communication
- (3) NRZ standard format
- (4) Characteristics of programmable serial port:
  - Data bit: 8 or 9 bits
  - Check bits: Even parity check, odd parity check, no check
  - Support 0.5, 1, 1.5 and 2 stop bits
- (5) Check control
  - Transmit the check bit
  - Check the received data
- (6) Independent transmitter and receiver enable bit
- (7) programmable baud rate generator, with baud rate of up to 4.5Mbits/s

- (8) Multiprocessor communication:
  - If the address does not match, it will enter the silent mode
  - Wake up from silent mode through idle bus detection or address flag detection
- (9) Synchronous transmission mode
- (10) Generation and detection of LIN break frame
- (11) Support the smart card interface of ISO7816-3 standard
- (12) Support IrDA protocol
- (13) Support hardware flow control
- (14) DMA can be used for continuous communication
- (15) State flag bit:
  - Transmission detection flag: The transmit register is empty, the receive register is not empty, and transmission is completed
  - Error detection flag: Overrun error, noise error, parity error, frame error
- (16) Multiple interrupt sources:
  - The transmit register is empty
  - Transmission is completed
  - CTS changed
  - The receive register cannot be empty
  - Overload error
  - Bus idle
  - Parity error
  - LIN break detection
  - Noise error
  - Overrun error
  - Frame error

## **18.4 Functional Description**

#### Table 63 USART Pin Description

| Pin         | Туре                        | Description                                 |

## 18.4.1 Single-line Half-duplex Communication

HDEN bit of USART\_CTRL3 register determines whether to enter the single-line half-duplex mode.

When USART enters single-line half-duplex mode:

- The CLKEN and LINMEN bit of USART\_CTRL2 register, and IREN and SCEN bits of USART\_CTRL3 register must be cleared.
- RX pin is disabled.
- TX pin should be configured as open-drain output and connected with RX pin inside the chip.
- Sending data and receiving data can not be carried out at the same time. The data cannot be received before they are sent. If needing to receive data, enabling receiving can be turned on only after TXCFLG bit of USART\_STS register is set to 1.
- If there is data conflict on the bus, software management is needed to allocate the communication process.

## 18.4.2 Frame Format

The frame format of data frame is controlled by USART\_CTRL1 register

- DBLCFG bit controls the character length, which can be set to 8 or 9 bits.
- PCEN bit controls to enable the check bit or not.
- PCFG bit controls the parity bit to be odd or even.

| DBLCFG bit | PCEN bit | USART data frame  |
|------------|----------|---|
| 0          | 0        | Start bit+8-bit data+stop bit                           |
| 0          | 1        | Start bit+7-bit data+odd-even parity check bit+stop bit |
| 1          | 0        | Start bit+9-bit data+stop bit                           |
| 1          | 1        | Start bit+8-bit data+odd-even parity check bit+stop bit |

#### Table 64 Frame Format

#### Configurable stop bit

Four different stop bits can be configured through STOPCFG bit of USART\_CTRL2 register.

- 1 stop bit: Default stop bit.
- 0.5 stop bit: Used when receiving data in smart card mode.
- 2 stop bits: Used in normal mode, single-line mode and hardware flow control mode.
- 1.5 stop bits: Used when sending and receiving data in smart card mode.

#### Check bit

PCFG bit of USART\_CTRL1 determines the parity check bit; when PCFG=0, it is even parity check, on the contrary, it is odd parity check.

- Even check: When the number of frame data and check bit 1 is even, the even check bit is 0; otherwise it is 1.
- Odd check: When the number of frame data and check bit 1 is even, the odd check bit is 1; otherwise it is 0.

## 18.4.3 Transmitter

When TXEN bit of the register USART\_CTRL1 is set, the transmit shift register will output data through TX pin and the corresponding clock pulses will be output through CK pin.

#### 18.4.3.1 Character Transmit

During transmitting period of USART, the least significant bit of the data will be moved out by TX pin first. In this mode, USART\_DATA register has a buffer between the internal bus and the transmitter shift register.

A data frame is composed of the start bit, character and stop bit, so there is a low-level start bit in front of each character; then there is a high-level stop bits the number of which is configurable.

#### Transmission configuration steps

- Set UEN bit of USART\_CTRL1 register to enable USART.
  - Decide the word length by setting DBLCFG bit of USART\_CTRL1 register.
  - Decide the number of stop bits by setting STOPCFG bit of USART\_CTRL2 register.
  - If multi-buffer communication is selected, DMA should be enabled in USART\_CTRL3 register.
  - Set the baud rate of communication in USART\_BR register.
  - Enable TXEN bit in USART\_CTRL1 register, and transmit an idle frame.
  - Wait for TXBEFLG bit of USART STS register to be set to 1.
  - Write data to USART\_DATA register (if DMA is not enabled, repeat steps 7-8 for each byte to be sent).
  - Wait for TXCFLG bit of USART\_STS register to be set to 1, indicating transmission completion.

Note: TXEN bit cannot be reset during data transmission; otherwise, the data on TX pin will be destroyed, which is because if the baud rate generator stops counting, the data being transmitted will be lost.

#### 18.4.3.2 Single-byte communication

TXBEFLG bit can be cleared by writing USART\_DATA register. When the TXBEFLG bit is set by hardware, the shift register will receive the data transferred from the data transmit register, then the data will be transmitted, and the data transmit register will be cleared. The next data can be written in the data register without covering the previous data.

- (1) If TXBEIEN in USART\_CTRL1 register is set to 1, an interrupt will be generated.
- (2) If USART is in the state of transmitting data, write to the data register to save the data to the DATA register, and transfer the data to the shift register at the end of the current data transmission.
- (3) If USART is in idle state, write to the data register, put the data into the shift register, start transmitting data, and set TXBEFLG bit to 1.
- (4) When a data transmission is completed and TXBEFLG bit is set, TXCFLG bit will be set to 1; at this time if TXCIEN bit in USART\_CTRL1 register is set to 1, an interrupt will be generated.

(5) After the last data is written in the USART\_DATA register, before entering the low-power mode or before closing the USART module, wait to set TXCFLG to 1.

#### 18.4.3.3 Break frame

The break frames are considered to receive 0 in a frame period. Setting TXBF bit of USART\_CTRL1 register can transmit a break frame, and the length of the break frame is determined by DBLCFG bit of USART\_CTRL1 register. If the TXBF bit is set, after completion of transmission of current data, the TX line will transmit a break frame, and after completion of transmission of break frame, the TXBF bit will be reset. At the end of the break frame, the transmitter inserts one or two stop bits to respond to the start bit.

Note: If the TXBF bit is reset before transmission of the break frame starts, the break frame will not be transmitted. To transmit two consecutive break frames, the TXBF bit should be set after the stop bit of the previous break symbol.

#### 18.4.3.4 Idle frame

The idle frame is regarded as a complete data frame composed entirely of 1, followed by the start bit of the next frame containing the data. Set TXEN bit of USART\_CTRL1 register to 1 and one idle frame can be set before the first data frame.

#### 18.4.4 Receiver

#### 18.4.4.1 Character receiving

During receiving period of USART, RX pin will first introduce the least significant bit of the data. In this mode, USART\_DATA register has a buffer between the internal bus and the receiver shift register. The data is transmitted to the buffer bit by bit. When fully receiving the data, the corresponding receiver register is not empty, then the user can read USART\_DATA.

#### **Receiving configuration steps**

- Set UEN bit of USART\_CTRL1 register to enable USART.
- Decide the word length by setting DBLCFG bit of USART\_CTRL1 register.
- Decide the number of stop bits by setting STOPCFG bit of USART\_CTRL2 register.
- If multi-buffer communication is selected, DMA should be enabled in USART\_CTRL3 register.
- Set the baud rate of communication in USART\_BR register.
- Set RXEN bit of USART\_CTRL1 to enable receiving.

Note:

- (1) RXEN bit cannot be reset during data receiving period; otherwise, the bytes being received will be lost.
- (2) In the process when the receiver is receiving a data frame, if overrun error, noise error or frame error is detected, the error flag will be set to 1.
- (3) When data is transferred from the shift register to USART\_DATA register, the RXBNEFLG bit of USART\_STS will be set by hardware.
- (4) An interrupt will be generated if RXBNEIEN bit is set.
- (5) In single buffer mode, the RXBNEFLG bit can be cleared by reading USART\_DATA register by software or by writing 0.
- (6) In multi-buffer mode, after each byte is received, RXBNEFLG bit of USART\_STS register will be set to 1, and DMA will read the data register to clear it.

#### 18.4.4.2 Break frame

When the receiver receives a break frame, USART will handle it as receiving a frame error.

#### 18.4.4.3 Idle frame

When the receiver receives an idle frame, USART will handle it as receiving an ordinary data frame; if IDLEIEN bit of USART\_CTRL1 is set, an interrupt will be generated.

#### 18.4.4.4 Overrun error

When RXBNEFLG bit of USART\_STS register is set to 1 and a new character is received at the same time, an overrun error will be caused. Only after RXEN is reset, can the data be transferred from the shift register to DATA register. RXBNEFLG bit will be set to 1 after receiving the byte. This bit needs to be reset before receiving the next data or serving the previous DMA request; otherwise, an overrun error will be caused.

#### When an overrun error occurs

- USART\_STS OVREFLG bit set to 1.
- The data in DATA register will not be lost.
- The data in the shift register received before will be overwritten, but the data received later will not be saved.
- If RXBNEIEN bit of USART\_CTRL1 is set to 1, an interrupt will be generated.
- When OVREFLG bit is set to 1, it means that the data has been lost. There are two possibilities:
  - When RXBNEFLG=1, the previous valid data is still on DATA register, and can be read.
  - When RXBNEFLG=0, there is no valid data in DATA register.
- The OVREFLG bit can be reset through read operation for USART STS and USART DATA registers.

#### 18.4.4.5 Noise error

When noise is detected in receiving process of the receiver:

- Set NE flag on the rising edge of RXBNEFLG bit of USART\_STS register.
- Invalid data is transmitted from the shift register to USART\_DATA register.

#### 18.4.4.6 Frame error

If the stop bit is not received and recognized at the expected receiving time due to excessive noise or lack of synchronization, a frame error will be detected.

When a frame error is detected in receiving process of the receiver:

- (1) Set the FEFLG bit of USART\_STS register.
- (2) Invalid data is transmitted from the shift register to USART\_DATA register.
- (3) In single byte communication, there is no interrupt, but in multi-buffer communication, an interrupt will be generated by setting the ERRIEN bit of USART\_CTRL3 register.

## 18.4.5 Baud Rate Generator

The baud rate division factor (USARTDIV) is a 16-digit number consisting of 12digit integer part and 4-digit decimal part. Its relationship with the system clock:

Baud rate=PCLK/16×(USARTDIV)

The system clock of USART2/3 is PCLK1, and that of USART1 is PCLK2. USART can be enabled only after the clock control unit enables the system clock.

## 18.4.6 Multi-processor Communication

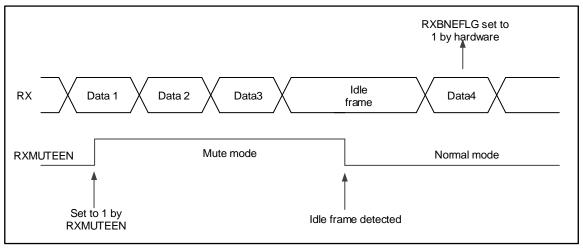

In multi-processor communication, multiple USARTs are connected to form a network. In this network, two devices communicate with each other, and the mute mode can be enabled for other devices not participating in the communication in order to reduce the burden of USART. In mute mode, no receive state bit will be set and all receive interrupts are disabled.

When mute mode is enabled, there are two ways to exit the mute mode:

- WUPMCFG bit is cleared and the bus is idle to exit the mute mode.
  - WUPMCFG bit is set and after receiving the address flag, it can exit the mute mode.

#### Idle bus detection (WUPMCFG=0)

When RXMUTEEN is set to 1, USART enters the mute mode, and it can be waken up from the mute mode when an idle frame is detected, meanwhile, the RXMUTEEN bit will be cleared by the hardware. RXMUTEEN can also be cleared by software.

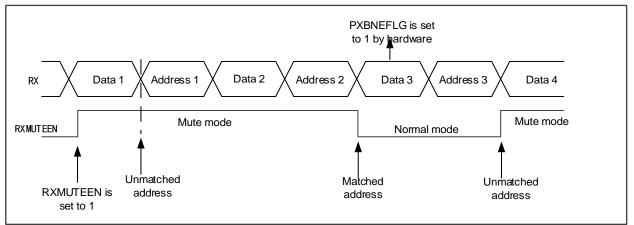

#### Figure 62 Idle Bus Exit Mute Mode

#### Address flag detection (WUPMCFG=1)

If the address flag bit is 1, this byte is regarded as the address. The storage address of lower four bits of the address bytes will first be compared with its own address when the receiver receives the address byte. If the addresses do not match, the receiver will enter the mute mode. If the addresses match, the receiver will wake up from the mute mode and be ready to receive the next byte. If the address byte is received again after exiting the mute mode, but the address does not match its own address, the receiver will enter the mute mode again.

#### Figure 63 Address Flag Exit Mute Mode

## 18.4.7 Synchronous Mode

The synchronous mode supports full duplex synchronous serial communication in master mode, and has one more signal line USART\_CK which can output synchronous clock than the asynchronous mode.

CLKEN bit of USART\_CTRL2 register decides whether to enter the synchronous mode.

When USART enters the synchronous mode:

- The LINMEN bit of USART\_CTRL2 register, and IREN, HDEN and SCEN bits of USART\_CTRL3 register must be cleared.
- The start bit and stop bit of data frame have no clock output.
- Whether the last data bit of data frame generates USART\_CK clock is decided by the LBCPOEN bit of USART\_CTRL2 register.
- The clock polarity of USART\_CK is decided by CPOL bit of USART\_CTRL2 register.
- The phase of USART\_CK is decided by the CPHA bit of USART\_CTRL2.
- The external CK clock cannot be activated when the bus is idle or the frame is disconnected.

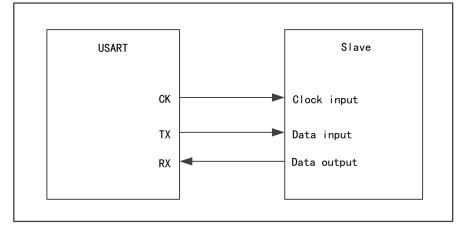

Figure 64 USART Synchronous Transmission Example

## Figure 65 USART Synchronous Transmission Timing Diagram (DBLCFG=0)

|                         | DBLCFG=0(8-bit data)  |
|-------------------------|---|

| CK(CPOL=0,CPHA=0)       |   |
| CK(CPOL=0,CPHA=1)       |   |
| CK(CPOL=1,CPHA=0)       |   |
| CK(CPOL=1,CPHA=1)       |   |
| TX (from master device) | Start bit Bit 0 Bit 1 Bit 2 Bit 3 Bit 4 Bit 5 Bit 6 Bit 7 Bit 8 Stop bit  |
| RX (from slave device)  | Bit 0         Bit 1         Bit 2         Bit 3         Bit 4         Bit 5         Bit 6         Bit 7         Bit 8 |

## 18.4.8 LIN Mode

LINMEN bit of USART\_CTRL2 register decides whether to enter LIN mode.

When entering LIN mode:

- All data frames are 8 data bits and 1 stop bit.
- The CLKEN bit and STOPCFG bit of USART\_CTRL2 register and IREN bit, HDEN bit and SCEN bit of USART\_CTRL3 register need to be cleared.

In LIN master mode, USART can generate break frame, and the detection length of break frame can be set to 10 bits and 11 bits through LBDLCFG bit of USART\_CTRL2. The break frame detection circuit is independent of USART receiver, and no matter in idle state or in data transmission state, RX pin can detect the break frame, and LBDFLG bit of USART\_STS register is set to 1; at this time, if LBDIEN bit of USART\_CTRL2 is enabled, an interrupt will be generated.

## Detection of break frame in idle state

In idle state, if a break frame is detected on RX pin, the receiver will receive a data frame of 0 and generate FEFLG.

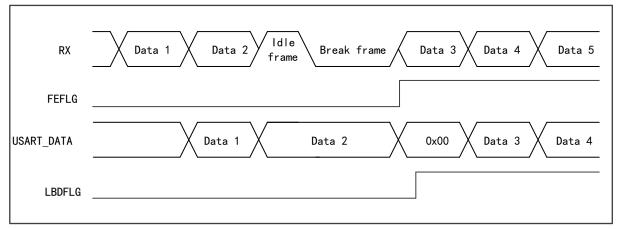

Figure 67 Break Frame Detection in Idle State

#### Detection of break frame in data transmission state

In the process of data transmission, if the RX pin detects the break frame, the currently transmitted data frame will generate FEFLG.

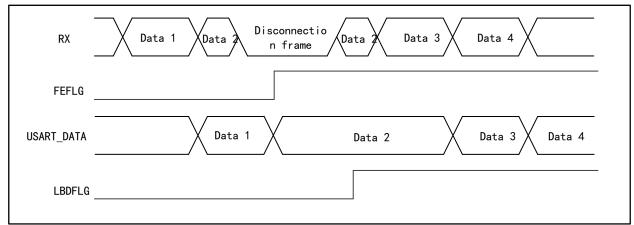

Figure 68 Break Frame Detection in Data Transmission State

## 18.4.9 Smart Card Mode

Smart card mode is a single-line half-duplex communication mode. The interface supports ISO7816-3 standard protocol and can control the reading and writing of smart cards that meet the standard protocol.

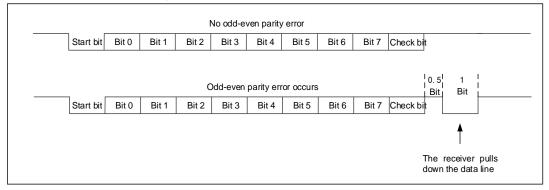

SCEN bit of USART\_CTRL3 register decides whether to enter the smart card mode.

When USART enters the smart card mode:

- The LINMEN bit of USART\_CTRL2 register, and IREN and HDEN bits of USART\_CTRL3 register must be cleared.
- The data frame format is 8 data bits and 1 check bit, and 0.5 or 1.5 stop bits are used. (To avoid switching between two configurations, it is recommended to use 1.5 stop bits when transmitting and receiving data)

- CLKEN bit of USART\_CTRL2 can be set to provide clocks for smart card.
- During the communication, when the receiver detects a parity error, in order to inform the transmitter that the data has not been received successfully, the data line will be pulled down after half a baud rate clock, and keep pulling down for one baud rate clock.
- The break frame has no meaning in smart card mode. A 00h data with frame error will be regarded as a data instead of break symbol.

#### Figure 69 ISO7816-3 Standard Protocol

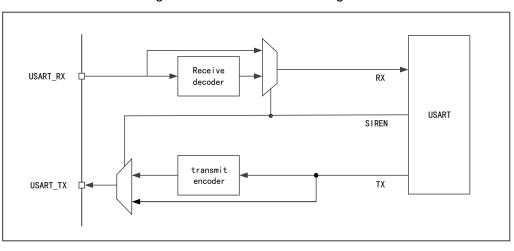

#### 18.4.10 Infrared (IrDA SIR) Function Mode

IrDA mode is a half-duplex protocol, transmitting and receiving data can not be carried out at the same time, and the delay between data transmitting and receiving should be more than 10ms.

IREN bit of USART\_CTRL3 register decides whether to enter the IrDA mode.

When USART enters the IrDA mode:

- The CLKEN bit, STOPCFG bit and LINMEN bit of USART\_CTRL2 register and HDEN bit and SCEN bit of USART\_CTRL3 register must be cleared.
- The data frame uses 1 stop bit and the baud rate is less than 115200Hz.
- Using infrared pulse (RZI) indicates logic 0, so in normal mode, its pulse width is 3/16 baud rate cycles. When IrDA is in low power mode, it is recommended that the pulse width be greater than three DIV frequency division clocks so as to ensure that this pulse can be detected by IrDA normally.

#### Figure 70 IrDA Mode Block Diagram

#### 18.4.11 Hardware Flow Control

The function of hardware flow control is to control the serial data flow between two devices through nCTS pin and nRTS pin.

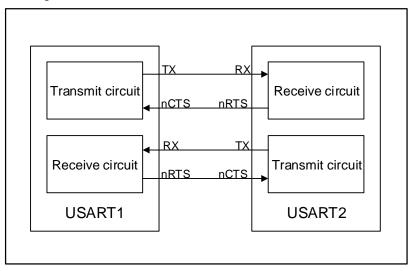

Figure 71 Hardware Flow Control between Two USARTs

#### **CTS flow control**

CTSEN bit of USART\_CTRL3 register determines whether CTS flow control is enabled. If CTS flow control is enabled, the transmitter will detect whether the data frame of nCTS pin can be sent. If TXBEFLG bit=0 for USART\_STS register and nCTS is pulled to low level, the data frame can be sent. If nCTS becomes high during transmission, the transmitter will stop transmitting after the current data frame is transmitted.

#### **RTS flow control**

RTSEN bit of USART\_CTRL3 register determines whether RTS flow control is enabled. If RTS flow control is enabled, when the receiver receives data, nRTS will be pulled to low level. When a data frame is received, nRTS will becomes high to inform the transmitter to stop transmitting data frame.

#### 18.4.12 DMA Multi-processor Communication

USART can access the data buffer in DMA mode in order to reduce the burden of processors.

#### Transmission in DMA mode

DMATXEN bit of USART\_CTRL3 register determines whether to transmit in DMA mode. When transmitting by DMA, the data in the designated SRAM will be transmitted to the buffer by DMA.

Configuration steps of transmission by DMA:

- Clear the TXCFLG bit of USART\_STS register.
- Set the address of SRAM memory storing data as DMA source address.
- Set the address of USART\_DATA register as DMA destination address.
- Set the number of data bytes to be transmitted.
- Set channel priority.

- Set interrupt enable.
- Enable DMA channel.
- Wait for TXCFLG bit of USART\_STS register to be set to 1, indicating transmission completion.

#### **Receive in DMA mode**

DMARXEN bit of USART\_CTRL3 register determines whether to receive by DMA. When receiving by DMA, every time one byte is received, the data in the receive buffer will be transmitted to the designated SRAM area by DMA.

Configuration steps of receiving by DMA:

- Set the address of USART\_DATA register as DMA source address.
- Set the address of SRAM memory storing data as DMA destination address.
- Set the number of data bytes to be transmitted.
- Set channel priority.
- Set interrupt enable.
- Enable DMA channel.

#### 18.4.13 Interrupt Request

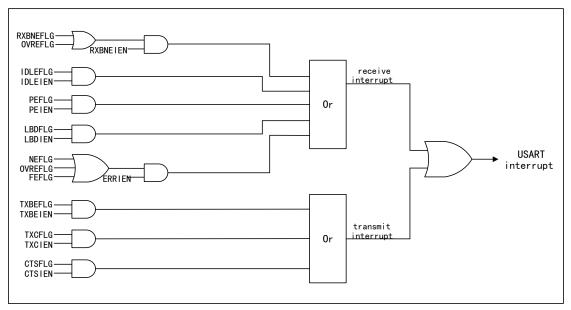

| Interrupt e                    | vent           | Event flag bit | Enable bit |
|--------------------------------|----------------|----------------|------------|
| The receive register c         | annot be empty | RXBNEFLG       |            |
| Overload e                     | error          | OVREFLG        | RXBNEIEN   |
| Line idle is de                | etected        | IDLEFLG        | IDLEIEN    |
| Odd-even par                   | ity error      | PEFLG          | PEIEN      |

| Packet Error Checking       | PEC                  |
| Address Resolution Protocol | ARP                  |

Table 68 Full Name and Abbreviation Description of Terms

### 19.2 Introduction

I2C is a short-distance bus communication protocol. In physical implementation, I2C bus is composed of two signal lines (SDA and SCL) and a ground wire. These two signal lines can be used for bidirectional transmission.

- Two signal lines, SCL clock line and SDA data line. SCL provides timing for SDA, and SDA transmits/receives data in series.
- Both SCL and SDA signal lines are bidirectional
- The ground is common when the two systems use I2C bus for communication.

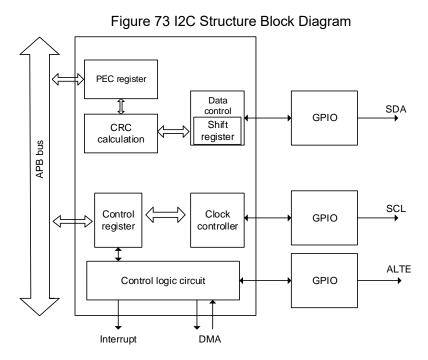

## **19.3 Main Characteristics**

- (4) Multi-master function
- (5) The master can generate the clock, start bit and stop bit
- (6) Slave function
  - Programmable I2C address detection
  - Double-address mode
  - Detection stop bit
- (7) 7-bit and 10-bit addressing mode
- (8) Response to broadcast
- (9) Two communication speeds
  - Standard mode
  - Fast mode

- (10) Programmable clock extension
- (11) State flag
  - Transmitter/Receiver mode flag
  - Flag for end of byte transmission
  - Flag of busy bus
- (12) Error flag
  - Arbitration loss
  - Acknowledgment error
  - Wrong start bit or stop bit detected
- (13) Interrupt source
  - Address/Data communication succeeded
  - Error interrupt
- (14) Support DMA function
- (15) Programmable PEC
  - Final transmission in transmission mode
  - PEC error check after the last byte is received
- (16) SMBus specific function
  - Hardware PEC
  - Address resolution protocol

## 19.4 Structure Block Diagram

The interface can be configured to the following modes:

- Slave transmitting
- Slave receiving
- Master transmitting
- Master receiving

In the initial state of I2C interface, the working mode is slave mode. After I2C interface sends the start signal, it will automatically switch from slave mode to master mode.

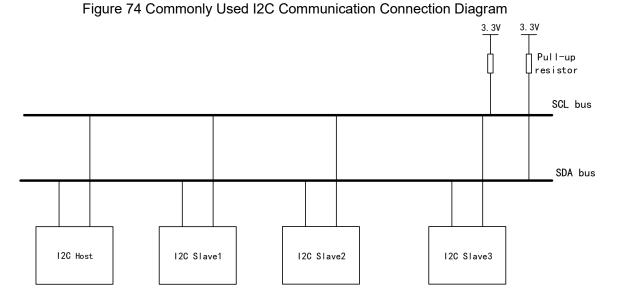

## **19.5 Functional Description**

#### Table 69 Description of Special Terms of I2C Bus

| Special terms    | Instruction   |
|------------------|---|
| Transmitter      | Device transmitting data to the bus   |
| Receiver         | Device receiving data from the bus  |
| Master           | Device that initiates data transmission, generates clock signals and ends data transmission |
| Slave            | Device addressed by master  |
| Multiple masters | Multiple masters that control the bus at the same time without destroying information       |
| Synchronous      | The process of synchronizing the clock signals between two or more devices                  |
| Arbitration      | If more than one master tries to control the bus at the same time, only one master can      |
| Arbitration      | control the bus, and the information of the controlled master will not be destroyed.        |

#### 19.5.1 I2C Physical Layer

The commonly used connection modes between I2C communication devices are shown in the figure below

#### Characteristics of physical layer

(1) Bus supporting multiple devices (signal line shared by multiple devices), which, in I2C communication bus, can connect multiple communication masters and communication slaves.

- (2) An I2C bus only uses two bus lines, namely, a bidirectional serial data line (SDA) and a serial clock line (SCL). The data line is used for data transmission, and the clock line is used for synchronous receiving and transmission of data.
- (3) Each device connected to the bus has an independent address (seven or ten bits), and the master addresses and accesses the slave device according to the address of the device.
- (4) The bus needs to connect the pull-up resistor to the power supply. When I2C bus is idle, the output is in high-impedance state. When all devices are idle, the output is in high-impedance state, and the pull-up resistor pulls the bus to high level.
- (5) Three communication modes: Standard mode (up to 100KHz), fast mode (up to 400KHz), and fast mode plus (up to 1MHz)
- (6) When multiple masters use the bus at the same time, to prevent the data conflict, the bus arbitration mode is adopted to determine which device occupies the bus
- (7) Can program setup and hold time, and program the high-level time and low-level time of SCL in I2C.

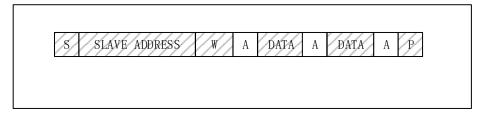

#### 19.5.2 I2C Protocol Layer

#### Characteristics of protocol layer

- (1) Data is transmitted in the form of frame, and each frame is composed of 1 byte (8 bits).
- (2) In the rising edge phase of SCL, SDA needs to keep stable and SDA changes during the period when SCL is low.
- (3) In addition to data frame, I2C bus also has start signal, stop signal and acknowledge signal.
  - Start bit: During the stable high level period of SCL, a falling edge of SDA starts transmission.
  - Stop bit: During the stable high level period of SCL, a rising edge of SDA stops transmission.
  - Acknowledge bit: Used to indicate successful transmission of one byte. After the bus transmitter (regardless of the master or slave) transmits 8-bit data, SDA will release (from output to input). During the ninth clock pulse, the receiver will pull down SDA to respond to the received data.

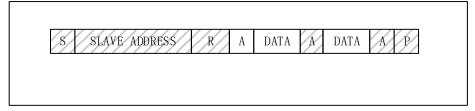

#### I2C communication reading and writing process

Figure 75 Master Writes Data to Slave

#### Figure 76 Master Reads Data from Slave

#### Remarks:

- (1) 1: This data is transferred from master to slave
- (2) S: Start signal
- (3) SLAVE ADDRESS: Slave address
- (4) : This data is transferred from slave to master
- (5) R/W: Selection bit of transmission direction
- (6) 1: Read
- (7) 0: Write
- (8) P: Stop signal

After the start signal is generated, all slaves will wait for the slave address signal sent by the master. In I2C bus, the address of each device is unique. When the address signal matches the device address, the slave will be selected, and the unselected slave will ignore the future data signal.

#### When the master direction is writing data

After broadcasting the address and receiving the acknowledge signal, the master will transmit data to the slave, and the data length is one byte. Every time the master sends one byte of data, it needs to wait for the acknowledge signal transmitted by the slave. After all the bytes have been transmitted, the master will transmit a stop signal (STOP) to the slave, indicating that the transmission is completed.

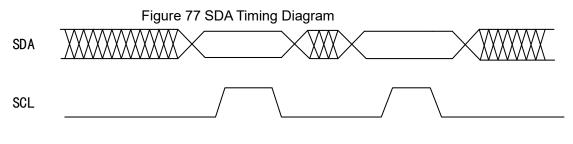

#### When the master direction is reading data

After broadcasting the address and receiving the acknowledge signal, the slave will transmit data to the master. The size of the data package is 8 bits. Every time the slave sends one byte of data, it needs to wait for the acknowledge signal of the master. When the master wants to stop receiving data, it needs to return a non-acknowledge signal to the slave, then the slave will stop transmitting the data automatically.

#### 19.5.3 Data Validity

In the process of data transmission, the data on SDA line must be stable when the clock signal SCL is at high level. Only when the SCL is at the low level, can the level state of SDA be changed, and the bit transmission of each data needs a clock pulse.

#### 19.5.4 Start and Stop Signals

All data transfer must have start signal (START) and stop signal (STOP).

Figure 78 START signal is defined as: when SCL is at high level, SDA will convert from high level to low level

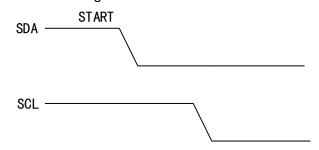

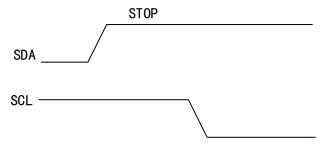

Figure 79 STOP signal is defined as: when SCL is at high level, SDA will convert from low level to high level

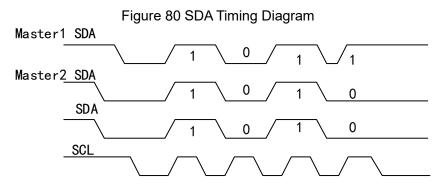

#### 19.5.5 Arbitration

Arbitration is also used to solve the bus control conflict in case of multiple masters. The arbitration process takes place on the master and has nothing to do with the slave.

The master can start transmission only when the bus is idle. Two masters may generate an effective START signal on the bus within the shortest hold time of the START signal. In this situation, it is required by arbitration to decide which master completes the transmission.

Arbitration is conducted by bit. During each arbitration, when SCL is high, each master will check whether the SDA level is the same as that sent by itself. The arbitration process needs to last for many bits. Theoretically, if two masters transmit exactly the same content, they can successfully transmit without arbitration failure. If one master transmits high level, but it is detected that SDA is at low level, an arbitration failure error will occur, the SDA output of the master will be closed, and the other master will complete its own transmission.

Note: Master 1 arbitration failure

#### 19.5.6 SMBus Specific Function

System management bus (SMBus) is a simple single-end double-wire bus, which can meet the requirements of lightweight communication.

SMBus is commonly used in computer motherboard, mainly for power transmission ON/OFF instructions. SMBus is the derivative bus of I2C. It is mainly used for communication of low-bandwidth devices on computer motherboard, and power-related chip.

#### Address resolution protocol

SMBus specification includes an address resolution protocol, which can realize dynamic address assignment. The dynamic identification hardware and software enable the bus to support hot plug-in, and the bus devices are automatically identified and assigned with the unique addresses,

#### SMBus alarm

SMBus alarm is an optional signal with an interrupt line for pins that are sacrificed to extend their control ability

#### 19.5.7 Error Flag Bit

Table 70 The following several error flag bits exist in I2C communication

| Error flag bit                             | Description of error flag bit  |
|--|--|
| Answer error flag bit (AEFLG)              | No answer received   |
| Bus error flag bit (BERRFLG)               | An external stop or start condition is detected  |
| Arbitration loss flag bit (ALFLG)          | Arbitration loss is detected by the interface  |
| Overrun/Underrun error flag bit (OVRURFLG) | In slave mode, the received data is not read out, the<br>next data has arrived, and an overrun error occurs.<br>The transmitting data clock has arrived, but the data<br>has not been written into the DATA register, and an<br>underrun error occurs. |
| Timeout or Tow error flag bit (TTEFLG)     | SCL is pulled down for more than a certain time  |
| PEC comparison error flag bit (PECEFLG)    | CRC values are not equal   |

#### 19.5.8 Message Error Check (PEC)

I2C module has a PEC module, which checks the message of I2C data by CRC-8 calculator. The CRC-8 polynomial used by the calculator is:  $C(x)=X^8+X^2+X+1$ .

When PECEN bit is set to 1 and PEC function is enabled, PEC module will calculate all data sent by I2C bus, including address data.

#### 19.5.9 DMA Mode

According to the software process of I2C, when the transmitter register is empty or the receiver register is full, MCU needs to write or read bytes, then we can complete the operation more quickly through the DMA function of I2C.

#### **DMA transmission**

Set the DMAEN bit in I2C\_CTRL2 register to enabe the DMA mode. When the transmitter register is empty (TXBEFLG is set to 1), the data will be directly loaded from the memory area to the DATA register through DMA.

#### **DMA receiving**

Set DMAEN bit in I2C\_CTRL2 register to enable DMA mode. When the receiving register is full (RXBNEFLG is set to 1), DMA will transmit the data in DATA register to the set memory area.

#### 19.5.10 I2C Interrupt

| Interrupt event   | Event flag bit | Interrupt control bit |  |
|---|----------------|-----------------------|--|
| Transmitting start bit completed                          | STARTFLG       |                       |  |
| Transmission completed/Address<br>matching address signal | ADDRFLG        |                       |  |
| 10-bit address head segment<br>transmission completed     | ADDR10FLG      | EVIEN                 |  |
| Received stop signal                                      | STOPFLG        |                       |  |
| Data byte transmission completed                          | BTCFLG         |                       |  |
| Receive buffer not empty                                  | RXBNEFLG       | EVIEN and BUFIEN      |  |
| Transmit buffer empty                                     | TXBEFLG        |                       |  |
| Bus error   | BERRFLG        |                       |  |
| Arbitration loss  | ALFLG          |                       |  |
| Answer failed   | AEFLG          |                       |  |
| Overrun/Underrun  | OVRURFLG       | ERRIEN                |  |
| PEC error   | PECEFLG        |                       |  |
| Timeout or Tlow error                                     | TTEFLG         |                       |  |
| SMBus alert   | ALERTEN        |                       |  |

Table 71 I2C Interrupt Request

## 19.6 Register Address Mapping

| Register name | Description                   | Offset address |
|---------------|-------------------------------|----------------|
| I2C_CTRL1     | Control register 1            | 0x00           |
| I2C_CTRL2     | Control register 2            | 0x04           |
| I2C_SADDR1    | Slave address register 1      | 0x08           |
| I2C_SADDR2    | Slave address register 2      | 0x0C           |
| I2C_DATA      | Data register                 | 0x10           |
| I2C_STS1      | State register 1              | 0x14           |
| I2C_STS2      | State register 2              | 0x18           |
| I2C_CLKCTRL   | Master clock control register | 0x1C           |
| I2C_RISETMAX  | Maximum rising time register  | 0x20           |
| I2C_SWITCH    | I2C Switch register           | 0x100          |

#### **Register Functional Description** 19.7

## **19.7.1 Control register 1 (I2C\_CTRL1)** Offset address: 0x00

Reset value: 0x0000

| 8     | BERRFLG  | RC_W0     | Bus error means exception of start bit or stop bit; when an error is  |
|       |          |           | detected, this bit can be set to 1 by hardware; this bit can be cleared after the software writes 0; when I2CEN=0, it can be cleared by hardware.   |
|       |          |           | Master Mode Arbitration Lost Flag   |
|       |          |           | 0: No arbitration loss  |
| 9     | ALFLG    | RC_W0     | 1: In case of arbitration loss, I2C interface will automatically switch back to<br>slave mode   |
|       |          |           | "Arbitration loss in master mode" means the master loses the control of buses; this bit is set to 1 by hardware; this bit can be cleared after the software writes 0; when I2CEN=0, it is cleared by hardware.                          |
|       |          |           | Acknowledge Error Flag  |
| 10    | AEFLG    | RC_W0     | 0: No acknowledgment error  |
| 10    | ALILU    | 1.0_00    | 1: Acknowledgment error occurred<br>This bit can be set to 1 by hardware; this bit can be cleared after the   |
|       |          |           | software writes 0; when I2CEN=0, it can be cleared by hardware.   |
| 11    | OVRURFLG | RC_W0     | Overrun/Underrun Flag<br>0: Not occur   |
|       |          |           |   |

| Field | Name     | R/W          | Description  |
|-------|----------|--------------|--|
|       |          |              | 1: Occurred  |
|       |          |              | This bit can be set to 1 by hardware when CLKSTRETCHD=1 and one of the following conditions is met:  |
|       |          |              | (1) In the slave receiving mode, when the data in the DATA register is not<br>read out, but a new data is received (this data will be lost), overrun<br>occurs;          |
|       |          |              | (2) In the slave transmission mode, no data is written in the data register but it still needs to transmit data (the same data is sent twice), and then underrun occurs. |
|       |          |              | This bit can be cleared by writing 0 by software; or be cleared by hardware when I2CEN=0.  |
|       |          |              | PEC Error in Reception Flag  |
|       |          |              | 0: No PEC error: when ACKEN=1, after receiving PEC, the receiver will<br>return ACKEN  |
| 12    | PECEFLG  | ECEFLG RC_W0 | 1: There is PEC error; regardless of the value of ACKEN, as long as PEC<br>is received, the receiver will return NACK  |
|       |          |              | This bit can be cleared by writing 0 by software; or be cleared by hardware when I2CEN=0.  |
| 13    |          |              | Reserved   |
|       |          |              | Timeout or Tlow Error Flag   |
|       |          |              | 0: No timeout error  |
|       |          |              | 1: When a timeout error occurs, in slave mode, the slave is reset and the bus is released; in master mode, the hardware transmit the stop bit.                           |
| 14    | TTEFLG   | EFLG RC_W0   | This bit can be set to 1 by hardware when timeout error occurs in any of<br>the following situations:  |
|       |          |              | (1) SCL maintains low level for more than 25ms;  |
|       |          |              | (2) SCL low-level extension time of the main device is more than 10ms;   |
|       |          |              | (3) SCL low-level extension time of the slave device is more than 25ms.  |
|       |          |              | This bit can be cleared by writing 0 by software; or be cleared by hardware when I2CEN=0.  |
|       |          |              | SMBus Alert Occur Flag   |
|       |          |              | 0: SMBus master mode, without alarm;   |
|       |          |              | SMBus slave mode, without alarm, SMBAlert pin level unchanged  |

## 20 Internal Integrated Circuit Interface (I2C3/4)

This module applies only to APM32F103xB.

## 20.1 Introduction

I2C bus is a two-wire serial interface, which consists of serial data line (SDA) and serial clock (SCL). These lines transmit information between devices connected to the bus. Each device is identified by a unique address and can work as a "transmitter" or "receiver", depending on the function of the device. When performing data transmission, the device can also be regarded as a master or slave. The master is the device that initiates data transmission on the bus and generates clock signals to enable the transmission. At this time, any device that is addressed is considered as slave.

I2C can run in standard mode (data rate is from 0 to 100 kb/s), fast mode (data rate is less than or equal to 400 kb/s), fast mode plus (data rate is less than or equal to 1000 kb/s), and high-speed mode (data rate is less than or equal to 3.4 kb/s).

I2C can only communicate with the devices in these modes as long as they are connected to the bus. Besides, the high-speed mode and fast-mode devices are downward compatible. For example, in a hybrid speed bus system, the high-speed mode devices can communicate with the devices in fast mode and standard mode. In the I2C bus system of 0-100kb/s, the fast-speed mode device can communicate with the standard mode device.

An example of high-speed mode devices is LCD display, high-bit count ADC and high-capacity EEPROM. These devices usually need to transmit mass data. Most maintenance and control applications, namely, the common use of I2C bus, usually operate at 100 kHz (in standard and fast-speed mode).

## 20.2 Functional Description

- Double-line I2C serial interface consists of a serial data line (SDA) and a serial clock (SCL).
- Three speeds:
  - Standard mode (0 to 100 Kb/s)
  - Fast-speed mode (≤ 400 Kb/s) or fast mode +(≤ 1000 Kb/s)
  - High-speed mode (≤ 3.4 Mb/s)
- Clock synchronization
- Master or slave I2C operation
- 7 or 10-bit address
- 7 or 10-bit combined transmission
- Bulk transfer mode
- Ignore CBUS address (used for sharing I2C old address of I2C bus)
- Transmitting and receiving buffers
- Bit and byte waiting at the speeds of processing all buses
- Programmable SDA hold time (T<sub>HD: DAT</sub>)
- Bus clear characteristics
- Dedicated transmit FIFO and receive FIFO; FIFO depth is 8, and FIFO bit width is 8 bits

#### 20.2.1 I2C Protocol

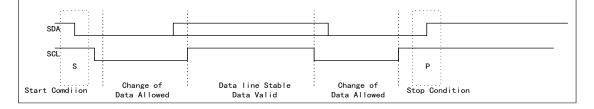

#### Start (START) and stop (STOP) conditions

When the bus is idle, both SCL and SDA signals are pulled up through the

external pull-up resistor on the bus. If the master wants to start transmission on the bus, it shall issue the start condition. This is defined as the high-low conversion of SDA signal, and SCL is 1. If the master wants to terminate the transmission, it shall issue the stop condition. This is defined as the low-high conversion of SDA line, and SCL is 1. The figure below shows the timing of start and stop conditions. When data is transmitted on the bus, SDA line must be stable if SCL is 1.

#### Addressing slave protocol

Two address formats: 7-bit address format and 10-bit address format

#### 7-bit address format

In the 7-bit address format, when bit 0 (R/W) is set to 0, the master writes to the slave. When the bit 0 (R/W) is set to 1, the master reads from the slave.

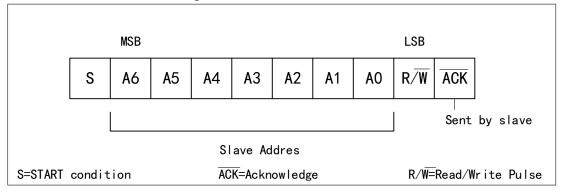

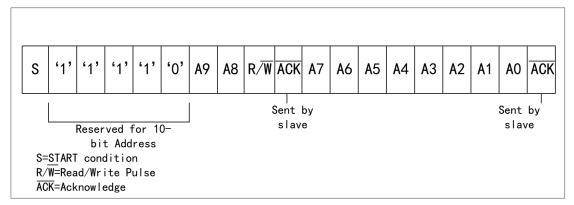

Figure 82 7-bit Address Format

#### 10-bit address format

In the 10 bit address format, two bytes are needed to transmit the 10 bit address. The transmission of the first byte contains the following bit definitions. The first five bits (bits 7:3) notify the slave that this is a 10-bit transmission, they are followed by the next two bits (bits 2:1) setting the slave address bits 9:8, and LSB bit (bit 0) as R/W bit. The second byte of the transmission sets the bits 7:0 of the slave address.

Figure 83 10-bit Address Format

#### Bit definition of I2C in the first byte

| Slave address | R/W bit | Description   |
|---------------|---------|---|
| 0000 000      | 0       | Broadcast call address. I2C puts the data in the receive buffer and triggers a broadcast call interrupt |
| 0000 000      | 1       | Start bit   |
| 0000 001      | х       | CBUS address. I2C ignores these addresses   |
| 0000 010      | х       | Reserved  |
| 0000 011      | х       | Reserved  |
| 0000 1xx      | х       | High-speed master (master) code   |

| 1100 001      | Х       | Reserved  |

#### Table 73 I2C Pin definition

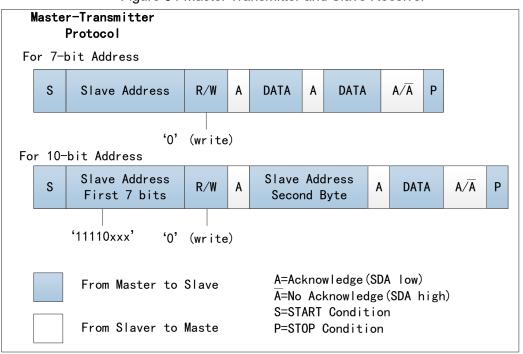

#### Transmit and receive protocol

As the master transmitter or master receiver, the master can initiate the data transmission and receiving between buses. The slave responds to the requests from the master to transmit data to the bus or receive data from the bus.

#### Master transmitter and slave receiver

All data are transmitted in byte format, and the number of bytes of each data for transmission is unrestricted. After the master transmit address and R/W bit or the master transmit data byte to the slave, the slave receiver must respond with acknowledgment signal (ACK). When the slave receiver does not respond to the ACK pulse, the master will can abort the transfer by transmitting a stop condition. The slave must keep the SDA line in high bit so that the master can abort the transfer. See the following figure for details.

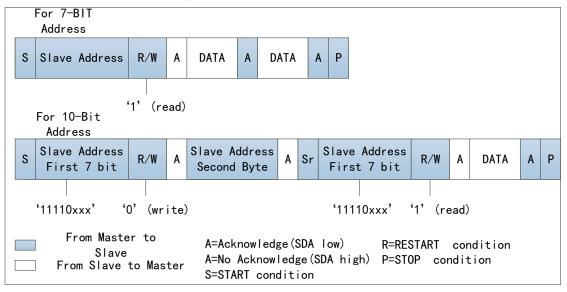

#### Figure 84 Master Transmitter and Slave Receiver

#### Master receiver and slave transmitter

If the master is receiving the data as shown in the figure below, after receiving one byte of data (except the last byte), the master will use an acknowledgment impulse to respond to the slave transmitter. Not transmitting acknowledgment pulse is a way for the master receiver to inform the slave transmitter that this is the last byte. The slave transmitter abandons the SDA line after detecting no acknowledgment (NACK) so that the master transmitter can issue the stop (STOP) condition.

The slave transmitter abandons the SDA line after detecting no acknowledgment (NACK) so that the master transmitter can issue the stop (STOP) condition. This is the same as the start condition, except that it occurs after the ACK pulse. When running in the master mode, I2C can communicate

with the same slave through transmission in different directions.

#### TXFIFO management and start (START), stop (STOP), and restart (RSTAEN)

Whenever TXFIFO becomes empty, the component will generate a stop (STOP) point on the bus. If the restart function is enabled, the component will generate a restart when the transmission direction in the TXFIFO command changes from read to write, and vice versa. If restart is not enabled, a stop will be generated in this case, and then a start will be generated.

The following timing diagram describes the behavior of I2C when TXFIFO becomes empty when it is running as the master transmitter.

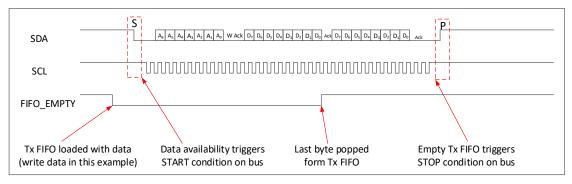

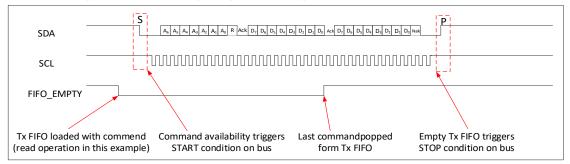

Figure 86 I2C Timing Diagram "Taking TXFIFO as Master Transmitter"

The following timing diagram describes the behavior of I2C when TXFIFO becomes empty when it is running as the master receiver.

Figure 87 I2C Timing Diagram "Taking TXFIFO as Master Receiver"

#### 20.2.2 Multi-master Arbitration

I2C bus protocol allows multiple masters to reside on the same bus. When there are two masters on the same I2C bus, if both masters attempt to control the bus by generating start condition at the same time, there will be an arbitration program.

Once a master controller (such as MCU) controls the bus, no other master controller can control the bus until the first master controller transmit a stop condition and the bus is idle.

Arbitration takes place on SDA line, while SCL line is 1. When another master transmits 0, the master transmits 1, the arbitration is lost and its data output phase is closed. The master that lost the arbitration can continue to generate the clock until the end of the byte transmission. If both masters are processing the same slave, arbitration may enter the data phase.

Once it is detected that it has lost arbitration with another master, I2C will stop

generating SCL (IC\_CLK\_oe).

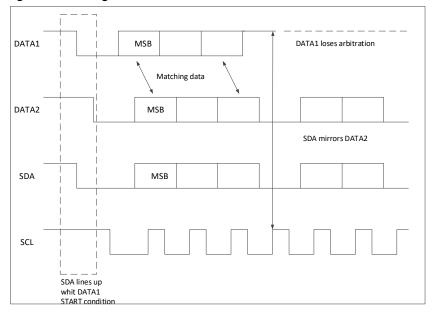

Figure 88 Timing of Arbitration of Two Master Controllers on the Bus

For high-speed mode, since each master is programmed with a unique highspeed main code, arbitration cannot enter the data phase. The 8-bit code is defined by the system designer and is set by writing it into the high-speed master mode code address register HSMC. Since these codes are unique, only one master code can win arbitration, which occurs at the end of high-speed master code transmission. The control of the bus is determined by the address or master code and the data sent by the competing master, so there is neither a central master nor any priority order on the bus.

Arbitration is not allowed between restart condition and data bit, stop condition and data bit, restart condition and stop condition.

#### 20.2.3 Clock Synchronization

When two or more masters attempt to transmit information on the bus at the same time, they must arbitrate and synchronize the SCL clock. Data is only valid in the high cycle of the SCL clock. Clock synchronization is performed by connecting lines to SCL signal. When the master converts the SCL clock to 0, the master starts to count the low time of the SCL clock, and converts the SCL clock signal to 1 at the beginning of the next clock cycle. However, if another master maintains the SCL line at 0, the master will enter a high wait state until the SCL clock row is converted to 1.

Then, all masters will report their high time, and the master with the shortest high time converts the SCL line to 0. Then, the master calculates its low time, and the one with the longest low time forces the other master to enter a high wait state. Therefore, a synchronized SCL clock will be generated. Or the slave can maintain the SCL line in a low position to slow down the timing on the I2C bus.

#### 20.2.4 IC\_CLK Frequency Configuration

When I2C is configured as standard speed (SS), fast speed (FS)/fast mode plus (FM+) or high-speed (HS) master control, the registers must be set before any I2C bus service occurs to ensure correct I/O timing.

Registers in different modes are shown in the table below:

| Mode                            | Register |  |  |  |
|---------------------------------|----------|--|--|--|
| Standard anadd (SS) mada        | SSCHC    |  |  |  |
| Standard speed (SS) mode        | SSCLC    |  |  |  |
| Fast speed (FS)/fast speed mode | HSCHC    |  |  |  |
| plus (FM+)                      | HSCLC    |  |  |  |
| High apood (HS)                 | HSCHC    |  |  |  |
| High speed (HS)                 | HSCLC    |  |  |  |

Table 74 Register in Different Modes

#### Minimum high and low count in SS, FS, FM+ and HS mode

When I2C is working as I2C master, in transmitting and receiving transmission:

- (1) The value of SSCLC and FSCLC registers must be greater than LSSSL+7.
- (2) The value of SSCHC and FSCHC registers must be greater than LSSSL+5.
- (3) If this component is programmed to support HS, the value of HSCLC register must be greater than HSSSL+7.
- (4) If this component is programmed to support HS, the value of HSCLC register must be greater than HSSSL+5.

Details about I2C high and low counts are as follows:

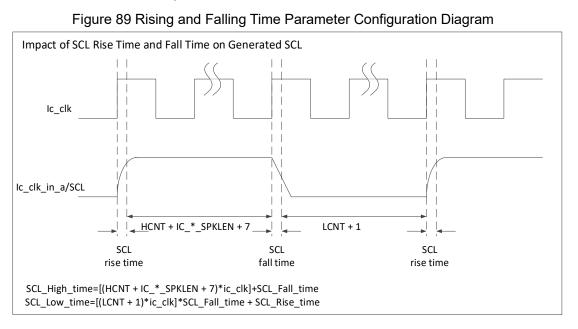

- (1) The minimum value of IC\_\*\_SPKLEN+7 of \*\_LCNT register is the time required to drive SDA after I2C is on the negative edge of SCL.
- (2) The minimum value of IC\_\*\_SPKLEN+5 of \*\_HCNT register is the time required to collect SDA samples because I2C is in the high-cycle period of SCL.
- (3) I2C adds a loop to the programmed \*\_LCNT value to generate the low cycle of SCL clock, which is because of the count logic of SCL low count to (\*\_ LCNT+1).
- (4) I2C adds IC\_\*\_SPKLEN+7 loop to the programmed \*\_HCNT value to generate the high cycle of SCL clock, which is because of the following factors.
  - Count ogic of SCL high count to (\*\_HCNT+1).
  - The digital filtering applied to SCL line will lead to delay of spklen+2IC\_clk cycle,
  - The filtering includes metastable removal and programmable peak suppression of SDA and SCL edges.
  - When I2C drives SCL from 1 to 0, the SCL high time is completed, and internal logic delay of three IC\_CLK cycles will be generated. Therefore, the minimum SCL low time that I2C can achieve is nine IC\_CLK cycles (7+1+1), while the minimum SCL high time is thirteen IC\_CLK cycles (6+1+3+3).

Note: The total high and low time of SCL generated by I2C master is also affected by the rising time and falling time of SCL line, as shown in the figure and equation. It should be noted that the rising and falling time parameters of SCL vary with external factors, such as:

- IO driver characteristics
- Pull-up resistance

• Total capacitance on SCL line, etc.

### 20.2.5 Operation Mode

#### 20.2.5.1 Slave mode operation

#### **Initial Configuration**

To use I2C as a slave device, perform the following steps:

- (1) Disable I2C by writing "0" to bit 0 of CTRL1 register
- (2) Write SLAADDR register (bit 9:0) to set slave address. This is the address of the I2C response
- (3) Write to CTRL0 register to specify which type of addressing (7 or 10 bits, set by bit 3) is supported by writing "0" to bit 6 (IC\_SLAVE\_DISABLE) and writing "0" to bit 0 (MST), and enable I2C in slave only mode.
- (4) I2C is enabled by writing "1" to bit 0 of CTRL1 register.

#### Single-byte slave transmitter operation

When another I2C master on the bus addresses I2C and requests data, I2C will act as a slave transmitter, and the following steps will occur:

- (1) Another I2C master starts I2C transmission, and its address matches the slave address in SLAADDR register of I2C.
- (2) I2C confirms the transmitting address and identifies the transmission direction to indicate that it is a slave transmitter.
- (3) I2C enables the RRIF interrupt (bit 5 of the RIS register) and keeps the SCL line low. It is in wait state until the software responds. If the RRIF interrupt has been masked because the INTEN [5] register (RRIE bit field) is set to 0, it is recommended that the hardware and/or software timing program be used to indicate that the CPU reads the RIS register periodically.

- The read operation indicating that RIS [5] (RRIF bit field) is set to 1 must be regarded as the equivalent operation of the enabled RRIF interrupt.
- Then the software must operate to satisfy I2C transmission.
- The timing interval used should be 10 times of the fastest SCL clock cycle that I2C can handle. For example, for 400 kb/s, the timing interval is 25µs.
- (4) If there is any data in the transmit FIFO before the read request is received, I2C enables the Tx ABRT interrupt (Bit 6 of the RIS register) to refresh the old data from the transmit FIFO. If the Tx-ABRT interrupt is masked, since the INTEN[6] register (TAIE bit field) is set to 0, it is recommended that the timing program (described in the previous step) or similar program be used again to read the RIS register.
  - Read indicating that Bit 6 (TAIF) is set to 1 must be regarded equivalent to the enabled TAIF interrupt.
  - The software does not need further operation.
  - The timing interval used should be similar to the time interval described for RIS[5] register in the previous step.
- (5) The software writes the data to the DATA register (by writing '0' to Bit 8).
- (6) Before the program, the software must clear the RRIF and TAIF interrupts (Bit 5 and Bit 6 respectively) of RIS register. If the RRIF and/or TAIF interrupts are masked, when the RRIF or TAIF bit is read to 1, clear of the RIS register will have been performed.
- (7) I2C releases SCL and transmits bytes.
- (8) The master can retain the I2C mainline by issuing the restart (RSTAEN) condition or release the mainline by transmitting a stop (STOP) condition.

#### Single-byte slave receiver operation

When another I2C master on the mainline addresses I2C and transmit data, I2C acts as a slave receiver, to perform the following steps:

- (1) Another I2C master starts an I2C transmission with the address in SLAADDR register that matches I2C slave address.
- (2) I2C confirms the address sent and identifies the direction of the transmission to indicate that I2C acts as a slave receiver.
- (3) I2C receives the bytes transmitted and puts them in the receive buffer.
- (4) I2C enables RFFIF interrupt (RIS[2] register). Since the INTEN[2] register is set to 0 or the TFT is set to a value greater than 0, if the RFFIF interrupt has been masked, it is recommended to implement a timing program for the periodic reading of STS1 register. The reading operation of the STS1 register with Bit 3 (RFNEF) set to 1 must be considered by the software as equivalent to the RFFIF interrupt enabled.
- (5) The software can read bytes (Bit 7:0) from DATA register.
- (6) Another master can retain the I2C mainline by issuing the restart (RSTAEN) condition or release the mainline by transmitting a stop (STOP) condition.

#### Slave transmission operation of bulk transmission

In the standard I2C protocol, all transmissions are single-byte transmission, and responds to the remote master read request by writing a byte to the FIFO of the slave. When the slave (slave transmitter) responds to a read request from the remote master (master receiver), at least one entry should be put in the TXFIFO of the slave transmitter. I2C is used to process more data in TXFIFO, so that the subsequent read requests can get more data without causing any interrupt.

Finally, this eliminates the possibility of occurrence of major delay between data interrupts every time only one entry is placed in TXFIFO.

This mode occurs only when I2C acts as a slave transmitter. If the remote master confirms the data sent by the slave and there is no data in the TXFIFO of the slave, I2C will keep the row in low bit while transmitting the read request interrupt (RRIF) and wait for the data to be written into the TXFIFO before the data is sent to the remote master.

If the RRIF interrupt is masked, since Bit 5 (RRIE) of the ISTS register is set to 0, it is recommended to use a timing program to activate periodic reading of the RIS register. The read operation of RIS with Bit 5 (RRIF) restored to 1 must be regarded as equivalent read operation to the RRIF interrupt mentioned in this section.

RRIF interrupts are triggered when reading requests. Like interrupts, they must be cleared when exiting the interrupt service processing routine (ISR). ISR allows you to write one or more bytes to TXFIFO. During transmission of these bytes to the master, if the master confirms the last byte, the slave must issue a RRIF again, which is because the master is requesting more data.

If knows in advance that the remote master is requesting an n-byte data packet, when another master addresses I2C and requests data, TXFIFO can be written in n bytes, and the remote master receives it as a continuous data stream. For example, the I2C slave will continue to transmit data to the remote master as long as the remote master is confirming the sent data and there is data available in TXFIFO. There is no need to keep the SCL row in low bit or issue a RRIF again.

If the remote master wants to receive n bytes from I2C, but writes the bytes greater than n into TXFIFO, when the slave completes transmitting the requested n bytes, the master will clear TXFIFO and ignore any redundant bytes.

I2C generates a transfer abort (TAIF) event to indicate the clearing of TXFIFO in this case. When ACK/NACK is needed, if NACK is received, the remote master will have all the required data. At this time, the state machine of the slave issues a flag to clear the remaining data in TXFIFO. This flag is transmitted to the processor bus clock domain where the FIFO is located, and the content of TXFIFO is cleared.

#### 20.2.5.2 Master mode operation

#### **Initial Configuration**

As the master of I2C, the destination address and address format can be changed without disabling I2C. The slave requires that the component be disabled before making any changes to the addressing.

(1) Write 0 to Bit 0 of CTRL1 register to disable I2C.

- (2) When the device is slave (Bit 3), write to CTRL0 register to set the maximum speed mode (Bit 2:1) supported by slave operation, and specify whether I2C starts transmission in 7/10-bit addressing mode.
- (3) Write the address of the I2C device to be addressed to the TARADDR register. It also indicates I2C will execute the general call or start byte command. The speed required for the transmission (7-bit or 10-bit address) initiated by the I2C master controller is controlled by the MAM bit field (Bit 12).
- (4) Apply only to transmission in high-speed mode. Write the main code required by I2C to HSMC register. The main code is defined by the programmer.
- (5) Write 1 to Bit 0 of CTRL1 register to enable I2C.
- (6) Now write the transmission direction and data to be sent to the DATA register. If the DATA register is written before I2C is enabled, the data and commands will be lost with the clearing of buffer when I2C is not enabled.

#### 20.2.6 Spike Suppression

I2C contains programmable peak suppression logic, which meets the requirements of I2C bus specification for SS/FS and HS modes.

This logic is based on the counter that monitors the input signals (SCL and SDA). Each signal has a separate counter (SCL and SDA). The number of IC\_CLK cycles can be programmed by the user, and the frequency of IC\_CLK and related peak length specifications should be considered in the calculation.

Each counter will be activated whenever the input signal value is changed. One of the following situations will occur, depending on the behavior of the input signal:

The input signal remains unchanged until the counter reaches the count limit. When this situation happens, the internal version of the signals will be updated with the input value and the counter will be reset and stopped. The counter will not restart until a new change to the input signal is detected.

Before the counter reaches the count limit, the input signal will change again. When this situation happens, the counter will be reset and stopped, but the internal version of the signal will not be updated. The counter remains in stop state until a new change on the input signal is detected.

The width of these registers is 8 bits, which can be read and written through APB interface. However, they can be written only when I2C is disabled. The minimum value that can be programmed into these registers is 1. If you attempt to write a value less than 1, 1 will be written.

# 20.3 Register Address Mapping

| Register name | Description                  | Offset address |
|---------------|------------------------------|----------------|
| CTRL0         | Control register             | 0x00           |
| TARADDR       | Destination address register | 0x04           |
| SLAADDR       | Slave address register       | 0x08           |

#### Table 75 I2C3/4 Register Address Mapping

| Register name | Description  | Offset address |
|---------------|--|----------------|
| HSMC          | Master address register  | 0x0C           |

# 20.4 Register Functional Description

# 20.4.1 I2C control register (CTRL0)

Offset address: 0x00 Reset value: 0x3E

| <b>-</b> ··· | Reset value: 0x3E |     |   |  |
|--------------|-------------------|-----|---|--|
| Field        | Name              | R/W | Description   |  |
| 0            | MST               | R/W | Master mode controller<br>Whether this bit controls 2C master<br>1: Enable master mode<br>0: Disable master mode  |  |
| 2:1          | SPEED             | R/W | I2C operating speed<br>These bits control the speed of I2C operation; it can be set only<br>when I2C is operated in master mode. Hardware can prevent<br>illegal values written by software. These bits must be properly<br>programmed for the slave mode as they are used to capture the<br>correct narrow band filter value according to the speed mode.<br>The programming value of this register can only be between 1<br>and 3; otherwise, the hardware will update the value of this<br>register to 3.<br>01: Standard mode (100kbit/s)<br>10: Fast-speed mode (<=400kbit/s) or fast-speed mode+<br>(<=1000Kbit/s)<br>11: High-speed mode (3.4Mbit/s)   |  |
| 3            | SAM               | R/W | Select the addressing mode<br>0: 7-bit addressing mode<br>1: 10-bit addressing mode   |  |
| 4            |                   |     | Reserved  |  |
| 5            | RSTAEN            | R/W | Transmitting the repeat start bit allowed<br>0: Transmitting repeat start bit not supported.<br>1: Transmitting repeat start bit supported.<br>Confirm whether RSTAEN can be sent when it acts as a master.<br>Some older slaves do not support processing RSTAEN;<br>however, RSTAEN is used in some I2C operations. When<br>restart is disabled, the main program is disabled to perform the<br>following functions:<br>transmit a start byte (START BYTE)<br>Perform any high-speed mode operation<br>High-speed mode operation<br>Perform direction changes in combination mode<br>Perform read operation with 10-bit address<br>By replacing RSTAEN with stop and following START,<br>discompose the operation into multiple I2C transmissions. If the<br>above operation is performed, Bit 6 (TAIF) of RIS register will be<br>set. |  |
| 6            | SLADIS            | R/W | Enable the slave mode<br>0: Slave mode enabled<br>1: Slave mode disabled  |  |

| Field | Name     | R/W | Description  |  |  |
|-------|----------|-----|--|--|--|
|       |          |     | This bit controls whether I2C has disabled its slave. After the reset is applied, you can choose to enable or disable the slave, which means that the software does not need to configure the slave. By default, the slave is always enabled (also in reset state). If you need to disable it after reset, set this bit to 1. If this bit is set (the slave is disabled), I2C will only run as the master and will not perform any operation that requires the slave.              |  |  |
| 7     | DSA      | R/W | <ul> <li>In slave mode:</li> <li>1: (ENABLED): As long as it is addressed, the slave will issue STPDIF interrupt</li> <li>0: (DISABLED): The slave always issues STPDIF interrupt</li> <li>Note: During general call addressing, if DSA=1b1, this slave will not issue STPDIF interrupt, even if the slave responds to the general call addressing by generating ACK. STPDIF interrupt is generated only when the transmission address matches the slave address (SAR).</li> </ul> |  |  |
| 8     | TFEIC    | R/W | This bit controls the generation of TFEIF interrupts, as<br>described in the RIS register.<br>1 (ENABLED): Control generation of TFEIF interrupt<br>0 (DISABLED): Default behavior of TFEIF interrupt  |  |  |
| 9     | RFFIE    | R   | This bit controls whether I2C maintains the bus when RXFIFO<br>is full<br>1: (ENABLED): Maintain the bus when RX_FIFO is full<br>0: (DISABLED): Overrun when RX_FIFO is full   |  |  |
| 10    | DSMA     | R   | In master mode:<br>1: (ENABLED): Enable STPDIF interrupt only when the master<br>is running<br>0: (DISABLED): Enable STPDIF interrupt regardless of whether<br>the master is running   |  |  |
| 31:11 | Reserved |     |  |  |  |

# 20.4.2 I2C destination address register (TARADDR)

Offset address: 0x4

| Field | Name | R/W | Description   |
|-------|------|-----|---|
| 8:0   | ADDR | R/W | This is the destination address of any master transaction.<br>In GENERAL_CALL, these bits will be ignored. To generate<br>START_BYTE, the CPU only needs to write these bits once. If ADDR<br>and SAR are the same, they can transmit to themselves, but FIFOs<br>are shared between master and slave, and they cannot transmit to<br>themselves. Only support simplex mode, and do not support duplex<br>mode. The master cannot transmit information to itself; it can only<br>transmit to one slave. |
| 10:9  | STA  | R/W | If the GCEN bit is set to 1, it indicates I2C performs the broadcast or<br>start byte command.<br>1: START_BYTE: start byte transmission<br>0: GENERAL_CALL: broadcast byte transmission  |
| 11    | GCEN | R/W | This bit indicates whether the software executes the device ID, or<br>general call, or start byte command.<br>1: (ENABLED): Enable the program transmitted by GENERAL_CALL<br>or START_BYTE<br>0: (DISABLED): Disable the program transmitted by<br>GENERAL_CALL or START_BYTE  |

| Field | Name     | R/W | Description  |  |  |
|-------|----------|-----|--|--|--|
| 12    | MAM      | R/W | <ul> <li>When I2C is the master, this bit is configured to start its transmission<br/>in 7-bit or 10-bit addressing mode.</li> <li>1: (ADDR_10BITS): Addressing 10-bit transmission format</li> <li>0: (ADDR_7BITS): Addressing 7-bit transmission format</li> </ul> |  |  |
| 31:13 | Reserved |     |  |  |  |

## 20.4.3 I2C slave address register (SLAADDR)

Offset address: 0x8 Reset value: 0x055

| Field | Name | R/W      | Description  |  |  |
|-------|------|----------|--|--|--|
| 9:0   | SAR  | R/W      | When I2C runs as a slave, SLAADDR will save the slave address. For 7-bit addressing, only use SLAADDR[6:0]. This register can write only when I2C interface is disabled, corresponding to CTRL1[0] register set to 0. Writing is invalid in other cases. |  |  |
| 31:10 |      | Reserved |  |  |  |

## 20.4.4 Main address register (HSMC)

Offset address: 0xC Reset value: 0x7

| Field | Name     | R/W | Description  |  |
|-------|----------|-----|--|--|
| 2:0   | HSMC     | R/W | This bit field saves the value of I2C HS mode main code. The HS mode master code is a reserved 8-bit code (00001xxx) and is not used for slave addressing or other purposes. Each masterhas its own unique main code; in the same I2C bus system, up to 8 high-speed mode masters can be provided. The valid values range from 0 to 7. This register disappears and returns 0, and becomes read-only. This register can write only when I2C interface is disabled, corresponding to CTRL1[0] register set to 0. Writing is invalid in other cases. |  |
| 31:3  | Reserved |     |  |  |

# 20.4.5 Data command register (DATA)

Offset address: 0x10

| Field | Name | R/W | Description  |  |  |  |
|-------|------|-----|--|--|--|--|
| 7:0   | DATA | R/W | This register contains the data to be transmitted or received on the I2C bus.<br>Reading this bit when writing is invalid. When reading this bit, the value<br>returned by these bits is the data received on the I2C interface.   |  |  |  |
| 8     | CMD  | W   | This bit controls to perform read or write operations.<br>When I2C acts as a slave, this bit will not control the direction. When it is the master, it controls the direction.<br>When you enter a command in TXFIFO, this bit will distinguish write and read commands. In slave receiving mode, this bit is useless. In slave transmitting mode, "0" means to transmit the data in DATA. When writing this bit, you should remember that if you attempt to perform a read operation after transmitting a general call command, a TAIF interrupt (Bit 6 of the RIS register) will be caused, unless Bit 11 (GCEN) of the TARADDR register has been cleared. If "1" is written to this bit after receiving the RRIF interrupt, a TAIF interrupt will occur.<br>0: Sequence data byte receiving, Main write command<br>1: Main read command |  |  |  |

| Field | Name | R/W      | Description   |  |  |
|-------|------|----------|---|--|--|
| 9     | STOP | R/W      | This bit controls stopping transmitting or receiving of data. |  |  |
| 31:10 |      | Reserved |   |  |  |

# 20.4.6 SCL high-bit counter register of standard-speed I2C clock (SSCHC)

Offset address: 0x14 Reset value: 0x190

| Field | Name     | R/W | Description  |
|-------|----------|-----|--|
| 10.0  |          | DAA | This register must be set before any I2C bus transaction to ensure the correct input/output (I/O) time. This register sets the high 16 bits of the SCL clock counter in standard speed mode. For more information, please see "IC_CLK Frequency Configuration".<br>This register can only write when I2C interface is disabled (CTRL1[0] register is 0).   |
| 13:0  | CNT      | R/W | 0). Writing is invalid in other cases. The minimum effective value is 6;<br>The hardware can prevent writing values less than this value, and if you attempt<br>to set a value, the set value of the result is 6. For the design of<br>APB_DATA_WIDTH=16, the programming sequence is very important for<br>ensuring correct operation of I2C. First program the lower byte. Then program<br>the upper byte. |
| 31:14 | Reserved |     |  |

# 20.4.7 SCL low-bit counter register of standard-speed I2C clock (SSCLC)

Offset address: 0x18 Reset value: 0x1D6

| Field | Name     | R/W | Description   |  |  |
|-------|----------|-----|---|--|--|
| 13:0  | CNT      | R/W | This register must be set before any I2C bus transaction to ensure the correct input/output (I/O) time. This register sets the low 16 bits of the SCL clock counter in standard speed mode. For more information, please refer to "IC_CLK Frequency Configuration". This register can only write when I2C interface is disabled (CTRL1[0] register is 0). Writing is invalid in other cases. The minimum effective value is 8; the hardware can prevent writing values less than this value, and if you attempt to set a value, the set value of the result is 8. For the design of APB_DATA_WIDTH=16, the programming sequence is very important for ensuring correct operation of I2C. First program the lower byte, and then program the upper byte. |  |  |
| 31:14 | Reserved |     |   |  |  |

# 20.4.8 SCL high-bit counter register of I2C clock of fast-speed mode or fast-speed plus mode (FSCHC)

Offset address: 0x1C

| Field | Name | R/W | Description   |
|-------|------|-----|---|
| 13:0  | CNT  | R/W | This register must be set before any I2C bus transaction to ensure<br>the correct input/output (I/O) time. This register sets the high 16 bits<br>of the SCL clock counter in fast speed mode or fast speed plus<br>mode. It is used to transmit the main code and START BYTE or<br>General CALL in fast speeed mode. For more information, please<br>see "IC_CLK Frequency Configuration". This register is 0 when reset,<br>and becomes read-only. This register can only write when I2C<br>interface is disabled (CTRL1[0] register is 0). The minimum effective<br>value is 6; the hardware can prevent writing values less than this<br>value, and if you attempt to set a value, it is set to 6. For the design<br>of APB DATA WIDTH=16, the programming sequence is very |

# 20.4.9 SCL low-bit counter register of I2C clock of fast-speed mode or fast-speed plus mode (FSCLC)

Offset address: 0x20 Reset value: 0x82

| Field | Name     | R/W | Description   |  |  |
|-------|----------|-----|---|--|--|
| 13:0  | CNT      | R/W | This register must be set before any I2C bus transaction to ensure<br>the correct input/output (I/O) time. This register sets the high 16 bits<br>of the SCL clock counter in fast speed mode or fast speed plus<br>mode. It is used to transmit the main code and START BYTE or<br>General CALL in fast speeed mode. For more information, please<br>see "IC_CLK Frequency Configuration". This register is 0 when reset,<br>and becomes read-only. This register can only write when I2C<br>interface is disabled (CTRL1[0] register is 0), and write is ineffective<br>in other cases. The minimum effective value is 8; the hardware can<br>prevent writing values less than this value, and if you attempt to set a<br>value, the set value of the result is 8. For the design of<br>APB_DATA_WIDTH=16, the programming sequence is very<br>important for ensuring correct operation of I2C. First program the<br>lower byte. Then program the upper byte. If the value is less than 8,<br>the count value will be changed to 8. |  |  |
| 31:14 | Reserved |     |   |  |  |

# 20.4.10 SCL high-bit counter register of high-speed mode I2C clock (HSCHC)

Offset address: 0x24 Reset value: 0x6

| Field | Name     | R/W | Description  |  |
|-------|----------|-----|--|--|
| 13:0  | CNT      | R/W | This register must be set before any I2C bus transaction to<br>ensure the correct input/output (I/O) time. This register sets the<br>high 16 bits of the SCL clock counter in high-speed mode. Please<br>see "IC_CLK Frequency Configuration". Setting of this register<br>depends on the bus. It is 60ns when 100pF is loaded; 120ns<br>when 400pF is loaded. This register is 0 when reset, and<br>becomes read-only. This register can only write when I2C<br>interface is disabled (CTRL1[0] register is 0), and write is<br>ineffective in other cases. The minimum effective value is 6; the<br>hardware can prevent writing values less than this value, and if<br>you attempt to set a value, the final set value is 6. For the design<br>of APB_DATA_WIDTH=16, the programming sequence is very<br>important for ensuring correct operation of I2C. First program the<br>lower byte. Then program the upper byte. |  |
| 31:14 | Reserved |     |  |  |

# 20.4.11 SCL low-bit counter register of high-speed mode I2C clock (HSCLC)

Offset address: 0x28 Reset value: 0x10

| Field | Name | R/W | Description  |
|-------|------|-----|--|
| 13:0  | CNT  | R/W | This register must be set before any I2C bus transaction to ensure<br>the correct input/output (I/O) time. This register sets the low 16 bits<br>of the SCL clock counter in high-speed mode. For more information,<br>please see "IC_CLK Frequency Configuration". Setting of this<br>register depends on the bus. It is 160ns when 100pF is loaded;<br>320ns when 400pF is loaded. This register is 0 when reset, and<br>becomes read-only. This register can only write when I2C interface<br>is disabled (CTRL1[0] register is 0), and write is ineffective in other<br>cases. The minimum effective value is 8; the hardware can prevent<br>writing values less than this value, and if you attempt to set a value,<br>the final set value is 8. For the design of APB_DATA_WIDTH=16,<br>the programming sequence is very important for ensuring correct<br>operation of I2C. First program the lower byte. Then program the<br>upper byte. If the value is less than 8, the count value will be<br>changed to 8. |

# 20.4.13 I2C interrupt enable register (INTEN)

Offset address: 0x30 Reset value: 0x8FF

| Field | Name   | R/W | Description   |
|-------|--------|-----|---|
| 0     | RFUIE  | R/W | This bit enables RFUIF interrupt in the ISTS register.<br>1: Enable<br>0: Disable   |
| 1     | RFOIE  | R/W | This bit enables RFOIF interrupt in the ISTS register.<br>1: Enable<br>0: Disable   |
| 2     | RFFIE  | R/W | This bit enables RFFIF interrupt in the ISTS register.<br>1: Enable<br>0: Disable   |
| 3     | TFOIE  | R/W | This bit enables TFOIF interrupt in the ISTS register.<br>1: Enable<br>0: Disable   |
| 4     | TFEIE  | R/W | This bit enables TFEIF interrupt in the ISTS register.<br>1: Enable<br>0: Disable   |
| 5     | RRIE   | R/W | This bit enables RRIF interrupt in the ISTS register.<br>1: Enable<br>0: Disable    |
| 6     | TAIE   | R/W | This bit enables TAIF interrupt in the ISTS register.<br>1: Enable<br>0: Disable    |
| 7     | RDIE   | R/W | This bit enables RDIF interrupt in the ISTS register.<br>1: Enable<br>0: Disable    |
| 8     | ACTIE  | R/W | This bit enables R_ACTIF interrupt in the ISTS register.<br>1: Enable<br>0: Disable |
| 9     | STPDIE | R/W | This bit enables STPDIF interrupt in the ISTS register.<br>1: Enable<br>0: Disable  |
| 10    | STADIE | R/W | This bit enables STADIF interrupt in the ISTS register.<br>1: Enable<br>0: Disable  |

| Field | Name     | R/W | Description  |  |
|-------|----------|-----|--|--|
| 11    | GCIE     | R/W | This bit enables GCIF interrupt in the ISTS register.<br>1: Enable<br>0: Disable |  |
| 31:12 | Reserved |     |  |  |

# 20.4.14 I2C original interrupt state register (RIS) Offset address: 0x34 Reset value: 0x00

| Field | Name  | R/W | Description   |
|-------|-------|-----|---|
| 0     | RFUIF | R   | Set when the receive buffer is empty and the processor<br>attempts to read the receive buffer from the DATA register.<br>If the module is disabled (CTRL1[0]=0), this bit holds its<br>level until the master state machine or slave state machine<br>enters the idle state. When I2CEN becomes 0, this<br>interrupt will be cleared.<br>1: RFUIF interrupt in active state<br>0: RFUIF interrupt in inactive state   |
| 1     | RFOIF | R   | If the receive buffer has been fully filled, it is set to the IC_RX_BUFFER_DEPTH and receives another byte from the external I2C device. I2C confirms this, but any data bytes received after FIFO is full will be lost. If the module is disabled (CTRL1[0]=0), this bit holds its level until the master state machine or slave state machine enters the idle state. When I2CEN becomes 0, this interrupt will be cleared.  |
|       |       |     | 0: RFOIF interrupt in inactive state  |
| 2     | RFFIF | R   | Set when the receive buffer reaches or exceeds the RFT<br>watermark in the RFT register. When the buffer level is<br>below the watermark, the hardware automatically clears it.<br>If the module is disabled (CTRL1[0] = 0), refresh the RX<br>FIFO and save it in the reset; therefore, the RX FIFO is not<br>full. Once CTRL1 Bit 0 is programmed to 0, this bit will be<br>cleared regardless of the activity to continue.<br>1: RFFIF interrupt in active state<br>0: RFFIF interrupt in inactive state   |
| 3     | TFOIF | R   | If the transmit buffer is filled to 16 and the processor<br>attempts to issue another I2C command by writing to the<br>DATA register, it is set during transmission. When the<br>module is disabled, this bit holds its level until the master<br>or slave state machine enters the idle state. When I2CEN<br>becomes 0, this interrupt will be cleared.<br>1: TFOIF interrupt in active state<br>0: TFOIF interrupt in inactive state  |
| 4     | TFEIF | R   | According to the TFEIC selection in CTRL0 register, the<br>behavior of TFEIF interrupt state is different.<br>When TFEIC=0: this bit is set to 1 when the transmit<br>buffer is at or below the watermark set in the TFT<br>register.<br>When TFEIC=1: when the transmit buffer is at or below<br>the watermark value set in the TFT register, this bit is<br>set to 1, and the transmission of address/data from the<br>internal shift register of the latest pop-up command is<br>completed.<br>When the buffer level exceeds the watermark, the<br>hardware automatically clears it. |

| Field | Name   | R/W | Description   |
|-------|--------|-----|---|
|       |        |     | <ul> <li>When CTRL1[0] is set to 0, TXFIFO is refreshed and saved in reset. The TXFIFO here appears to have no data, so this bit is set to 1, provided it is active in the master or slave state machine. When there is no more activity, and I2CEN=0, this bit is set to 0.</li> <li>1: TFEIF interrupt in active state</li> <li>0: TFEIF interrupt in inactive state</li> </ul>   |
| 5     | RRIF   | R   | This bit is set to 1 when I2C acts as a slave server and<br>another I2C master attempts to read data from I2C. I2C<br>keeps the I2C bus in the waiting state (SCL=0) until the<br>interrupt is served, which means that the slave machine<br>has been addressed by the remote master requesting data<br>transmission. The processor must respond to the interrupt<br>and write the requested data to the DATA register. This bit<br>is set to 0 after the processor reads IC_CLRRIF register.<br>1: RRIF interrupt in active state<br>0: RRIF interrupt in inactive state   |
| 6     | TAIF   | R   | This bit indicates that if I2C acts as an I2C transmitter, it<br>cannot complete the expected operation of transmit FIFO<br>content. This situation can occur on either the I2C master<br>or the I2C slave, which is called "transfer abort".<br>When this bit is set to 1, the TAS register indicates the<br>cause of the transfer abort.<br>Note: I2C only refreshes/resets/clears TX_FIFO when any<br>event tracked by the TAS register causes the transfer<br>abort. Before reading the register IC_CLTAIF, TXFIFO<br>keeps this refresh state. After performing this read,<br>TXFIFO can receive more data bytes from APB interface.<br>1: TAIF interrupt in active state<br>0: TAIF interrupt in inactive state   |
| 7     | RDIF   | R   | This bit masks the RDIF interrupt in the ISTS register.<br>1: RDIF interrupt unmasked<br>0: RDIF interrupt masked   |
| 8     | ACTIF  | R   | This bit captures I2C activity and remains set until it is<br>cleared. There are four ways to clear it:<br>I2C is disabled;<br>Read AIC register;<br>Read ICF register;<br>System reset.<br>Once this bit is set, it remains set unless one of these four<br>ways is used to clear it. Even if the I2C module is idle, this<br>bit remains set until cleared, indicating that there is activity<br>on the bus.<br>1: RAW_INTR_ACTIF interrupt in active state<br>0: RAW_INTR_ACTIF interrupt in inactive state<br>When I2C acts as a slave transmitter, if the master does<br>not confirm the bytes transmitted, set the bit to 1. This<br>occurs in the last byte transmitted, indicating that the<br>transmission has been completed.<br>1: RDIF interrupt in active state<br>0: RDIF interrupt in inactive state |
| 9     | STPDIF | R   | Indicate whether a stop condition has occurred on the I2C interface, regardless of the I2C running in slave or master mode.<br>In slave mode:<br>If CTRL0 register DSA=1b1, the STPDIF interrupt is only issued when the slave machine is addressed.  |

| Field | Name    | R/W | Description  |
|-------|---------|-----|--|
|       |         |     | Note: During general call addressing, if DSA=1b1, this<br>slave will not issue an STPDIF interrupt, even if the slave<br>responds to the general call addressing by generating an<br>ACK.<br>STPDIF interrupt is generated only when the transmission<br>address matches the slave address (SAR).<br>If CTRL0 register DSA=1b0, the STOP DET interrupt will<br>be issued regardless of whether it is addressed.<br>In master mode:<br>If CTRL0 register DSMA=1b1, the STPDIF interrupt will be<br>issued only when the master is active.<br>If CTRL0 register DSMA=1b0, the STPDIF interrupt will be<br>issued regardless of whether the master is active.<br>If CTRL0 register DSMA=1b0, the STPDIF interrupt will be<br>issued regardless of whether the master is active.<br>1: STPDIF interrupt in active state<br>0: STPDIF interrupt in inactive state |
| 10    | STADIF  | R   | <ul> <li>Indicate whether a start (START) or restart (RSTAEN) condition has occurred on the I2C interface, regardless of the I2C running in slave or master mode.</li> <li>1: STADIF interrupt in active state</li> <li>0: STADIF interrupt in inactive state</li> </ul>   |
| 11    | GCIF    | R   | Set only when a general call addressing is received and<br>the address is confirmed. It remains set until it is cleared<br>by disabling I2C or when the CPU reads Bit 0 of the GCIC<br>register. I2C stores the received data in the Rx buffer.<br>1: GCIF interrupt in active state<br>0: GCIF interrupt in inactive state  |
| 12    | RSTADIF | R   | Indicate whether a restart (RSTAEN) condition occurs on<br>the I2C interface when I2C is operating in slave mode and<br>addressing the slave. Enable only when<br>IC_SLV_RSTADIF_EN=1. Note: However, in high-speed<br>mode or during initial byte transmission, restart before the<br>address field according to I2C protocol. In this case, when<br>a restart is issued, the slave is not addressing slave, so<br>I2C will not generate RSTADIF interrupt.<br>1: RSTADIF interrupt in active state<br>0: RSTADIF interrupt in inactive state   |
| 13    | MOHIF   | R   | Indicate whether master holds bus, and whether TXFIFO<br>is empty. Enable only when<br>I2C_DYNAMIC_TAR_UPDATE=1 and<br>IC_EMPTYFIFO_HOLD_MASTER_EN=1.<br>1: MOHIF interrupt is active<br>0: MOHIF interrupt is inactive  |
| 31:14 |         |     | Reserved   |

# 20.4.15 I2C receiver FIFO watermark register (RFT)

Offset address: 0x38

| Field | Name | R/W      | 2/W Description  |  |  |  |  |  |
|-------|------|----------|--|--|--|--|--|--|
| 7:0   | RFT  | R/W      | The receive FIFO watermark controls the data bits that trigger the RFFIF interrupt (Bit 2 in RIS register). If it is greater than this value, the interrupt will be triggered. The valid range is 0-255, but the hardware does not allow setting this value to be greater than the buffer depth. If you try to do this, the actual value will be the maximum depth of the buffer. The value 0 sets the watermark of 1 bit, and the value 255 sets the watermark of 256 bits. |  |  |  |  |  |
| 31:8  |      | Reserved |  |  |  |  |  |  |

#### 20.4.16 I2C transmit FIFO watermark register (TFT)

Offset address: 0x3C

Reset value: 0x00

| Field | Name     | R/W | Description  |  |  |  |  |  |  |
|-------|----------|-----|--|--|--|--|--|--|--|
| 7:0   | TFT      | R/W | The transmit FIFO watermark controls trigger TFEIF interrupt (Bit 4 in RIS register); the interrupt will be triggered if the value is less than this value. The valid range is 0-255, and the additional restriction is that it cannot be set to be greater than the buffer depth. If you try to do this, the actual value will be the maximum depth of the buffer. The value 0 sets the watermark of 0 bit, and the value 255 sets the watermark of 255 bits. |  |  |  |  |  |  |
| 31:8  | Reserved |     |  |  |  |  |  |  |  |

## 20.4.17 Clear combined and single interrupt register (ICF)

Offset address: 0x40

| Res   | Reset value: 0x00 |     |  |  |  |  |  |
|-------|-------------------|-----|--|--|--|--|--|
| Field | Name              | R/W | Description  |  |  |  |  |
| 0     | ICF               | R   | Read this register to clear the combined interrupt, all separate<br>interrupts, and TAS registers. This bit does not clear the interrupts<br>that can be cleared by hardware, but clears the interrupts that can be<br>cleared by software.<br>For clearing TAS exception, refer to Bit 9 of the TAS register. |  |  |  |  |
| 31:1  | Reserved          |     |  |  |  |  |  |

#### 20.4.18 Clear RFUIT interrupt register (RFUIC)

Offset address: 0x44 Reset value: 0x00

| Field | Name     | R/W | Description  |  |  |
|-------|----------|-----|--|--|--|
| 0     | RFUIC    | R   | Read this register to clear the RFUIF interrupt (Bit 0) of RIS register. |  |  |
| 31:1  | Reserved |     |  |  |  |

#### 20.4.19 Clear RFOIF interrupt register (RFOIC)

Offset address: 0x48

Reset value: 0x00

| Field | Name     | R/W | Description  |  |  |
|-------|----------|-----|--|--|--|
| 0     | RFOIC    | R   | Read this register to clear the RFOIF interrupt (Bit 1) of RIS register. |  |  |
| 31:1  | Reserved |     |  |  |  |

## 20.4.20 Clear TFOIF interrupt register (TFOIC)

Offset address: 0x4C

Reset value: 0x00

| Field | Name     | R/W | Description  |  |  |
|-------|----------|-----|--|--|--|
| 0     | TFOIC    | R   | Read this register to clear the TFOIF interrupt (Bit 3) of RIS register. |  |  |
| 31:1  | Reserved |     |  |  |  |

#### 20.4.21 Clear RRIF interrupt register (RRIC)

Offset address: 0x50 Reset value: 0x00

| Field | Name     | R/W | Description  |  |  |
|-------|----------|-----|--|--|--|
| 0     | RRIC     | R   | Read this register to clear the RRIF interrupt (Bit 5) of RIS register |  |  |
| 31:1  | Reserved |     |  |  |  |

#### 20.4.22 Clear TAIF interrupt register (TAIC)

Offset address: 0x54 Reset value: 0x00

| Field | Name     | R/W | Description  |  |  |
|-------|----------|-----|--|--|--|
| 0     | TAIC     | R   | Read this register to clear the TAIF interrupt (Bit 6) of RIS register and TAS register. This can also relese the TXFIFO from the refresh/reset state, thus allowing more writes to the TXFIFO. For clearing TAS exception, refer to MSTDIS bit of the TAS register. |  |  |
| 31:1  | Reserved |     |  |  |  |

#### 20.4.23 Clear RDIF interrupt register (RDIC)

Offset address: 0x58

Reset value: 0x00

| Field | Name     | R/W | Description   |  |  |
|-------|----------|-----|---|--|--|
| 0     | RDIC     | R   | Read this register to clear the RDIF interrupt (Bit 7) of RIS register. |  |  |
| 31:1  | Reserved |     |   |  |  |

## 20.4.24 Clear ACTIF interrupt register (AIC)

Offset address: 0x5C Reset value: 0x00

|       | 1        |     |  |  |  |  |  |
|-------|----------|-----|--|--|--|--|--|
| Field | Name     | R/W | Description  |  |  |  |  |
| 0     | AIC      | R   | If I2C is no longer active, read this register to clear the ACTIF<br>interrupt. If the I2C module is still active on the bus, continue to<br>set the ACTIF interrupt bit. If the module is disabled and there is<br>no other activity on the bus, the hardware will automatically clear<br>this interrupt bit. Read this register to obtain the value of ACTIF<br>interrupt state (Bit 8) of RIS register. |  |  |  |  |
| 31:1  | Reserved |     |  |  |  |  |  |

## 20.4.25 Clear STPDIF interrupt register (STPDIC)

Offset address: 0x60

Reset value: 0x00

| Field | Name     | R/W | Description   |  |  |
|-------|----------|-----|---|--|--|
| 0     | STPDIC   | R   | Read this register to clear the STPDIF interrupt (Bit 9) of RIS register. |  |  |
| 31:1  | Reserved |     |   |  |  |

## 20.4.26 Clear STADIF interrupt register (STADIC)

Offset address: 0x64 Reset value: 0x00

| Field | Name     | R/W | Description  |  |  |
|-------|----------|-----|--|--|--|
| 0     | STADIC   | R   | Read this register to clear the STADIF interrupt (Bit 10) of RIS register. |  |  |
| 31:1  | Reserved |     |  |  |  |

## 20.4.27 Clear GCIF interrupt register (GCIC)

Offset address: 0x68

Reset value: 0x00

| Field | Name     | R/W | Description  |  |  |
|-------|----------|-----|--|--|--|
| 0     | GCIC     | R   | Read this register to clear the GCIF interrupt (Bit 11) of RIS register. |  |  |
| 31:1  | Reserved |     |  |  |  |

# 20.4.28 I2C start register (CTRL1)

Offset address: 0x6c

| Field | Name     | R/W | Description   |  |
|-------|----------|-----|---|--|
| 0     | I2CEN    | R/W | Control to enable I2C or not<br>0: Disable I2C (TX and RX FIFO remain in erased state)<br>1: Enable I2C<br>When I2C is active, the software can disable it. However, it<br>must be ensured that I2C is correctly disabled. A program is<br>recommended in the "disable I2C" description. When I2C is<br>disabled, the following may occur:<br>TXFIFO and RXFIFO refresh<br>The state bit in the ISTS register is still active until I2C enters<br>the idle (IDLE) state.<br>If the module is transmitting, it will stop and delete the content<br>of the transmit buffer after the current transmission is<br>completed. If the module is receiving, I2C will stop the current<br>transmission at the end of the current byte and will not confirm<br>the transmission. |  |
| 1     | ABR      | R/W | After setting, the controller enables the transfer abort.<br>0: Abort is not started or has been completed<br>1: Abort operation in progress<br>By setting this bit, the software can abort I2C transfer in master<br>mode. The software can only set this bit when enabling (I2CEN)<br>has been set; otherwise, the controller will ignore any write to<br>the abort (ABR) bit. Once set, the software cannot clear the<br>abort bit. In response to the abort, the controller issues a STOP<br>and refreshes the TXFIFO after the current transmission is<br>completed, and then sets the TX_ABORT interrupt after the<br>abort operation . The abort bit is automatically cleared after the<br>abort operation.  |  |
| 2     | тсв      | R/W | <ol> <li>Even if TXFIFO has data for transmission, it will also block<br/>transmission of the data on I2C bus.</li> <li>When the first data in TXFIFO is available, the data will be<br/>automatically transmitted on I2C bus.</li> <li>Note: When TXFIFO is empty (STS1[2]==1) and the master is<br/>in idle state (STS1[5]==0), set TCB bit and the master will stop<br/>executing the command. Command in TXFIFO will not be<br/>executed before TCB bit is set.</li> </ol>  |  |
| 31:3  | Reserved |     |   |  |

#### 20.4.29 I2C state register (STS1)

Offset address: 0x70

Reset value: 0x06

This is a read-only register, used to indicate current transmission state and FIFO state. The state register can read at any time. There is no field request interrupt in this register. When I2C is disabled by writing 0 to Bit 0 of CTRL1 register: Bit 1 and bit 2 are set to 0, Bit 3 and Bit 10 are set to 0. When the master or slave state machine is idle and I2CEN=0: Bit 5 and Bit 6 are set to 0

| Field | Name     | R/W | Description  |  |  |
|-------|----------|-----|--|--|--|
| 0     | ACTF     | R   | I2C active state<br>1: I2C in active state<br>0: I2C in idle state   |  |  |
| 1     | TFNFF    | R   | Transmit FIFO not full. Set when the transmit FIFO contains one or<br>more idle positions; clear when FIFO is full.<br>1: TXFIFO not full<br>0: TXFIFO full  |  |  |
| 2     | TFEF     | R   | Transmit FIFO is completely empty. When the transmit FIFO is<br>completely empty. set this bit. When it contains one or more valid<br>entries, clear this field. This bit field does not request interrut.<br>1: TXFIFO empty<br>0: TXFIFO not empty |  |  |
| 3     | RFNEF    | R   | Receive FIFO is not empty. Set this bit when the receive FIFO contains<br>one or more entries; clear it when the receive FIFO is empty.<br>1: Rx FIFO not empty<br>0: Rx FIFO empty  |  |  |
| 4     | RFFF     | R   | Receive FIFO is completely full. Set this field when Receive FIFO is<br>completely full. Clear this field when receive FIFO contains one or<br>more empty positions.<br>1: RXFIFO full<br>0: RXFIFO not full   |  |  |
| 5     | MAF      | R   | Master in active state. Set this bit when the master is not in idle state.<br>1: The master is not idle<br>0: The master is idle   |  |  |
| 6     | SAF      | R   | Slave in active state. Set this bit when the slave is not in idle (IDLE)<br>state.<br>1: The slave is not idle<br>0: The slave is idle   |  |  |
| 31:7  | Reserved |     |  |  |  |

#### 20.4.30 I2C transmit FIFO stock register (TFL)

Offset address: 0x74 Reset value: 0x00

Table 76 Full Name and Abbreviation Description of Terms

## 21.2 Introduction

Serial peripheral interface (SPI) provides data transmitting and receiving functions based on SPI protocol, which allows chips to communicate with external devices in half duplex, full duplex, synchronous and serial modes, and can work in master or slave mode.

## 21.3 Main Characteristics

#### 21.3.1 Main Characteristics of SPI

- (1) Master and slave operation with 3-wire full duplex synchronous transmission and receiving
- (2) Simplex synchronous transmission can be realized by two wires (the third bidirectional data line can be included/not included)
- (3) Select 8-bitt or 16-bit transmission frame format
- (4) Support multiple master device mode
- (5) Support special transmission and receiving mark and can trigger interrupt
- (6) Have SPI bus busy state flag
- (7) Fast communication of master/slave communication, up to 18MHZ
- (8) Clock polarity and phase are programmable

- (9) Data sequence is programmable; select MSB or LSB first
- (10) Interrupt can be triggered by master mode fault, overrun and CRC error flag
- (11) Have DMA transmit and receive buffers
- (12) Calculation, transmission and verification can be conducted through hardware CRC

# 21.4 Functional Description

#### 21.4.1 Description of SPI Signal Line

Table 77 SPI Signal Line Description

| Pin name | Description   |
|----------|---|
| SCK      | Master device: SPI clock outputs                                      |
| JOK      | Slave device: SPI clock inputs  |
|          | Master device: Input the pin and receive data                         |
| MISO     | Slave device: Output the pin and send data                            |
|          | Data direction: From slave device to master device                    |
|          | Master device: Output the pin and send data                           |
| MOSI     | Slave device: Input the pin and receive data                          |
|          | Data direction: From master device to slave device                    |
|          | Software NSS mode: NSS pin can be used for other purposes.            |
|          | Hardware NSS mode of master device:                                   |
| NSS      | NSS outputs, in single-master mode,                                   |
| 100      | NSS OFF output: Operation of multiple master environments is allowed, |
|          | Slave hardware NSS mode: The NSS signal is set to low level as the    |
|          | chip selection signal of the slave                                    |

#### 21.4.2 Phase and Polarity of Clock Signal

The clock polarity and clock phase are CPOL and CPHA bits of SPI\_CTRL1 register.

Clock polarity CPOL means the level signal of SCK signal line when SPI is in idle state.

- When CPOL=0, SCK signal line is in idle state and at low level
- When CPOL=1, SCK signal line is in idle state and at high level

Clock phase CPHA means the sampling moment of data

- When CPHA=0, the signal on MOSI or MISO data line will be sampled by the "odd edge" on SCK clock line.
- When CPHA=1, the signal on MOSI or MISO data line will be sampled by the "even edge" on SCK clock line.

SPI can be divided into four modes according to the states of clock phase CPHA and clock polarity CPOL.

| SPI mode | СРНА | CPOL | Sampling<br>moment | Idle SCK clock |
|----------|------|------|--------------------|----------------|
| 0        | 0    | 0    | Odd edge           | Low level      |
| 1        | 0    | 1    | Odd edge           | High level     |
| 2        | 1    | 0    | Even edge          | Low level      |
| 3        | 1    | 1    | Even edge          | High level     |

Table 78 Four Modes of SPI

#### 21.4.3 Data Frame Format

Set MSB or LSB to be first by configuring LSBSEL bit in SPI\_CTRL1 register. Select to transmit/receive in 8/16-bit data frame format by configuring DFLSEL bit in SPI\_CTRL1 register.

#### 21.4.4 NSS Mode

Software NSS mode: Select to enable or disable this mode by configuring SSEN bit of SPI\_CTRL1 register, and the internal NSS signal level is driven by ISSEL bit of SPI\_CTRL1 register.

Hardware NSS mode:

- Turn on NSS output: When SPI is in master mode, enable SSOEN bit, NSS pin will be pulled to low level and SPI will automatically enter the slave mode.
- Turn off NSS output: Operation is allowed in multiple master environments.

#### 21.4.5 SPI Mode

#### 21.4.5.1 SPI master mode

In master mode, generate serial clock on SCK pin

Master mode configuration

- Configure MSMSEL=1 in SPI\_CTRL1 register
- Select the polarity and phase by configuring CPOL and CPHA bits in SPI\_CTRL1 register.
- Select 8/16-bit data frame format by configuring DFLSEL bit in SPI\_CTRL1 register
- Select LSB or MSB first by configuring LSBSEL in SPI\_CTRL1 register
- NSS configuration:
  - NSS pin works in input mode: in hardware mode, it is required to connect NSS pin to high level during the entire data frame transmission; in software mode, it is required to set SSEN bit and ISSEL bit in SPI\_CTRL1 register
  - NSS works in output mode and it is required to configure SSOEN bit of SPI\_CTRL2 register
- Enable SPI by configuring SPIEN bit in SPI\_CTRL1 register

In master mode: MOSI pin is data output, which MISO is data input

#### 21.4.5.2 SPI slave mode

In slave mode, SCK pin receives the serial clock transmitted from the master device

Configuration of slave mode

- Configure MSMSEL=0 in SPI\_CTRL1 register
- Select the polarity and phase by configuring CPOL and CPHA bits in SPI\_CTRL1 register.
- Select 8/16-bit data frame format by configuring DFLSEL bit in SPI\_CTRL1 register
- Select LSB or MSB first by configuring LSBSEL in SPI\_CTRL1 register
- NSS configuration:
  - In hardware mode: NSS pin must be at low level in the whole data frame transmission process
  - In software mode: Set SSEN bit in SPI\_CTRL1 register and clear ISSEL bit
- Enable SPI by configuring SPIEN bit in SPI\_CTRL1 register

In slave mode: MOSI pin is data input, which MISO is data output

#### 21.4.5.3 Half-duplex communication of SPI

#### One clock line and one bidirectional data line

- Enable this mode by setting BMEN of SPI CTRL1 register
- Control the data line to be input or output by setting BMOEN bit of SPI\_CTRL1 register
- SCK pin is used as clock, MOSI pin is used in master device to transmit data, and MISO pin is used in slave device to transmit data

#### 21.4.5.4 Simplex communication of SPI

#### One clock line and one unidirectional data line

In this mode, SPI module can only receive or only transmit

Transmit-only mode:

- Data are transmitted on Transmit pin (MOSI in master mode, MISO in slave mode)
- Then the receive pin can be used as general I/O (MISO in master mode, MOSI in slave mode).

Receive-only mode:

- In master mode, enable SPI to initiate communication, clear SPEN pin of SPI\_CTRL1 register, and it will stop receiving data immediately, not needing to read BSYFLG flag (always 1).
- Slave mode: When NSS is pulled to low level, SPI will receive all the time as long as SCK has clock pulse.

In receive-only mode, SPI output can be closed by setting RXOMEN bit in SPI\_CTRL1 register. At this time, release the transmit pin (MOSI in master mode, MISO in slave mode), which can be used for other functions.

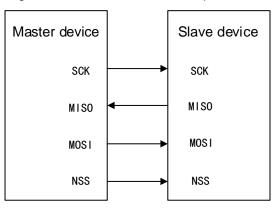

#### 21.4.6 Data Transmit and Receive Process in Different SPI Modes

|   | Table 79 Run Mode of SPI | 1                                   |
|---|--------------------------|-------------------------------------|
| Mode  | Configure                | Data pin                            |
| Full duplex mode of master device                 | BMEN=0, RXOMEN=0         | MOSI Transmits; MISO<br>receives    |
| Unidirectional receiving<br>mode of master device | BMEN=0, RXOMEN=1         | MOSI is not used; MISO<br>receives  |
| Bidirectional Transmit mode of master device      | BMEN=1,BMOEN=1           | MOSI Transmits; MISO is<br>not used |
| Bidirectional receiving mode of master device     | BMEN=1, BMOEN=0          | MOSI is not used; MISO<br>receives  |

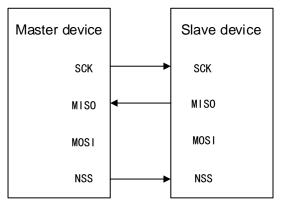

| Mode   | Configure        | Data pin                                 |
|--|------------------|--|
| Full duplex mode of slave device                 | BMEN=0, RXOMEN=0 | MOSI receives, and MISO<br>transmits     |
| Unidirectional receiving<br>mode of slave device | BMEN=0, RXOMEN=1 | MOSI receives, while MISO<br>is not used |
| Bidirectional Transmit<br>mode of slave device   | BMEN=1, BMOEN=1  | MOSI is not used, and<br>MISO transmits  |
| Bidirectional receiving<br>mode of slave device  | BMEN=1, BMOEN=0  | MOSI receives, while MISO<br>is not used |

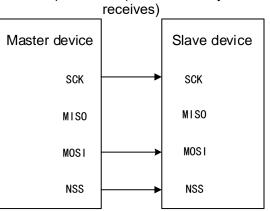

Figure 90 Connection in Full Duplex Mode

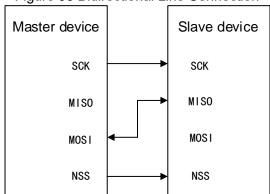

Figure 93 Bidirectional Line Connection

#### 21.4.6.1 Transmitting and receiving of processed data

#### Data transmission

After the mode configuration is completed, the SPI module is enabled to remain idle.

Master mode: The software writes a data frame to the transmit buffer, and the transmission process starts

Slave mode: The SCK signal on the SCK pin starts to jump, while the NSS pin level is low, and the transmission process starts (before starting data transmission, make sure that the data has been written to the transmit buffer in advance).

When SPI is transmitting a data frame, it will load the data frame from the data buffer to the shift register, and then start to transmit data. After one bit of data frame is sent, TXBEFLG is set to 1. If you need to continue to transmit data, the software needs to wait until TXBEFLG=1 writes data to the SPI\_DATA register. (TXBEFLG flag is set to 1 by hardware and cleared by software).

#### **Data receiving**

BSYFLG flag is always set to 1 in the data transmission process.

At the last edge of the sampling clock, the received data is transferred from the shift register to the receive buffer; set the RXBNEFLG flag, and the software reads the data in data register (SPI\_DATA) to obtain the content of the receive buffer; if RXBNEIEN bit of SPI\_CTRL2 register is set, an interrupt will be generated, and after data is read, the BSYFLG flag will be automatically cleared.

#### 21.4.6.2 Full duplex transmitting and receiving mode in master/slave device

#### Full duplex mode in master device

- After writing data to SPI\_DATA register (transmit buffer), data transmission starts.
- When SPI transmits the first bit of data, the data is transferred from the transmit buffer to the shift register and then transferred to the MOSI pin serially according to the sequence.
- The data received on MISO pin is serially transferred to SPI\_DATA register (receive buffer) according to the sequence.

Transmitting and receiving are synchronous.

#### Full duplex mode under slave device

- When the slave device receives the clock signal and the first data bit appears on the MOSI pin, data transmission starts, and the subsequent data bits will be transferred to the shift register in turn.
- When SPI Transmits the first bit of data, the data is transferred from the transmit buffer to the shift register, and then transferred to the MISO pin serially according to the sequence.
- The software must ensure that the data to be sent is written before the SPI master device starts to transmit data.

Transmitting and receiving are synchronous

#### Full duplex transmitting and receiving process under master/slave device

- (1) Enable SPI module: Configure SPIEN=1 of SPI\_CTRL1 register.
- (2) Write the first data to be sent to SPI\_DATA register, and the TXBEFLG flag will be cleared.
- (3) Wait until TXBEFLG flag bit is set to 1 (control by hardware), and write the second data bit to be sent.
- (4) Wait until RXBNEFLG flag bit is set to 1 (control by hardware), read the first received data in the SPI\_DATA register, at the same time, clear the RXBNEFLG flag (cleared by software). Repeat the operation, and Transmit and receive data at the same time.
- (5) Wait until RXBNEFLG=1 and receive the last data.
- (6) Wait until TXBEFLG=1 and close SPI module after BSYFLG=0.

#### 21.4.6.3 Bidirectional Transmitting mode of master/slave device

#### **Bidirectional transmission of master device**

- Write data to SPI\_ DATA register, and the transmission starts
- The data in the transmit buffer is transferred to the shift register in parallel, and then transferred to the MOSI pin serially according to the sequence.

#### **Bidirectional transmission of slave device**

- When the slave device receives the clock signal and the first data bit appears on the MISO pin, data transmission starts.
- At the same time, the data to be sent by the transmit buffer is transferred to the shift register in parallel, and then sent to the MISO pin in serial (before data transmission, make sure that the data has been written to the transmit buffer in advance).

#### Bidirectional transmission process of master/slave device

- (1) Enable SPI module: Configure SPIEN=1 of SPI\_CTRL1 register.
- (2) Write the first data to be sent to SPI\_DATA register, and the TXBEFLG flag will be cleared.
- (3) Wait until TXBEFLG=1, write the second data, repeat the operation and send the subsequent data
- (4) After writing the last data, wait for TXBEFLG=1 and BSYFLG=0 and transmission is completed

#### 21.4.6.4 One-way/Two-way receiving mode under master/slave device

- (1) Enable SPI module: Configure SPIEN=1 of SPI\_CTRL1 register.
- (2) In the master device: Generate SCK clock immediately, and continuously receive data before SPI is closed.
- (3) Slave device: When SPI master device pulls down NSS and generates clock, receive data.
- (4) Wait until the RXBNEFLG flag is set to 1, read data through SPI\_DATA, and repeat the operation to receive data.

#### 21.4.7 CRC Function

SPI module contains two CRC computing units, which are used for data receiving and data transmission respectively.

CRC computing unit is used to define polynomials in SPI\_CRCPOLY register.

Enable CRC computing by configuring CRCEN bit in SPI\_CTRL1 register; at the same time, reset the CRC register (SPI\_RXCRC and SPI\_TXCRC).

To obtain the CRC value of transmission calculation, after the last data is written to the transmit buffer, it is required to set CRCNXT bit of SPI\_CTRL1; indicate that the hardware Transmits the CRC value after the last data is sent, and the CRCNXT bit will be cleared; at the same time, compare the values of CRC and SPI\_RXCRC, and if they do not match, it is required to set CRCEFLG bit of SPI\_STS register, and after ERRIEN bit of SPI\_CTRL2 regiser is set, an interrupt will occur.

Note:

- (1) If SPI is under slave device and CRC function is used, CRC computing will continue when NSS pin is at high level. For example, when the master device communicates with multiple slave devices alternately, the above situation will occur, so it is necessary to avoid faulty operation of CRC.
- (2) In the process of a slave device from being unselected (NSS is at high level) to being selected (NSS is at low level 0), it is required to clear the CRC value at both ends of the master and slave devices to keep the next CRC computing results of the master and slave devices synchronized.
- (3) When SPI is in slave mode, CRC computing can be enabled after the clock is stable.
- (4) When the SPI clock frequency is too high, the CPU operation will affect the SPI bandwidth. It is recommended to use DMA mode to avoid the reduction of SPI speed.
- (5) When the SPI clock frequency is too high, during the CRC transmission period, the CPU utilization frequency is reduced, and the function call is disabled in the CRC transmission process to avoid errors when receiving the last data and CRC.
- (6) When NSS hardware mode is used in slave mode, NSS pin should be kept low during data transmission and CRC transmission period.

#### Sequence of clearing CRC values

- (1) SPI Disable (SPIEN=0)
- (2) Clear CRCEN bit
- (3) Set CRCEN bit to 1
- (4) Enable SPI (SPIEN=1)

#### 21.4.8 DMA Function

For high-speed data transmission, the request/response DMA mechanism in SPI improves the system efficiency and can transfer data to SPI transmit buffer promptly, and the receive buffer can read the data in time to prevent overflow.

When SPI only Transmits data, it is only needed to enable DMA transmission channel; when SPI only receives data, it is only needed to enable DMA receiving channel.

DMA function of SPI mode can be enabled by configuring TXDEN and RXDEN bits of SPI CTRL2 register.

- When Transmitting: When TXBEFLG flag bit is set to 1, issue the DMA request, DMA controller writes data to SPI\_DATA register, and then the TXBEFLG flag bit will be cleared.
- When receiving: When setting RXBNEFLG flag bit to 1, issue the DMA request, DMA controller reads data from SPI\_DATA register, and then RXBNEFLG flag bit is cleared.

By monitoring BSYFLG flag bit, confirm whether SPI communication is over after DMA has transferred all data to be sent in Transmitting mode, which can avoid damaging the transmission of last data.

#### **DMA function with CRC**

By the end of communication, if SPI enables both CRC operation and DMA function, Transmiting and receiving of CRC bytes will be completed automatically.

At the end of data and CRC transmission, if CRCEFLG flag bit of SPI\_STS register is set to 1, it indicates that an error occurred during transmission.

#### 21.4.9 SPI Disable

After data transmission is over, end the communication by closing SPI module. In some configurations, if SPI is closed before data transmission is completed, data transmission error may be caused. Different methods are required in different operation modes to close SPI

#### Full duplex mode under master/slave device

- (1) Wait until RXBNEFLG flag bit is set to 1, and receive the last data
- (2) Wait until TXBEFLG flag bit is set to 1
- (3) Wait for clearing BSYFLG flag bit
- (4) Disable SPI (set SPIEN=0 of SPI\_CTRL1 register)

#### One-way/Two-way receive-only mode under master/slave device

- (1) Wait No. n-1 RXBNEFLG flag bit is set to 1
- (2) Wait for one SPI clock cycle before SPI is closed (set SPIEN=0 of SPI\_CTRL1 register)
- (3) Before entering the stop mode, wait until the last RXBNEFLG flag bit is set to 1

#### Receive-only/Two-way receiving mode in slave mode

SPI can be closed at any time (set SPIEN=0 of SPI\_CTRL1 register) and it will be closed when the transmission is over. If you want to enter the stop mode, wait until BSYFLG flag bit is cleared.

#### 21.4.10 SPI Interrupt

#### 21.4.10.1 State flag bit

There are three flag bits for fully monitoring the state of SPI bus

#### Transmit buffer empty flag TXBEFLG

TXBEFLG=1 indicates that the transmit buffer bit is empty, and the next data to be sent can be written. When the data is written to SPI\_DATA register, clear the TXBEFLG flag bit.

#### Receive buffer non-empty flag RXBNEFLG

RXBNEFLG=1 indicates that the receive buffer contains valid data and the data can be read through SPI\_DATA register; then clear the RXBNEFLG flag

#### **Busy flag BSYFLG**

BSYFLG flag is set and cleared by hardware, which can indicate the state of SPI communication layer. When BSYFLG=1, it indicates SPI is communicating, but in the two-line receiving mode under the master device, BSYFLG=0 during the period of receiving of data.

BSYFLG flag can be used to detect whether transmission is over to avoid damaging the last transmitted data.

BSYFLG flag bit can be used to avoid conflict when writing data in multi-master mode.

BSYFLG flag will be cleared when the transmission ends (except for continuous communication in master mode), SPI is closed and the master mode fails.

BSYFLG=0 between data item and data item when communication is discontinuous.

When communication is continuous:

- In master mode: BSYFLG=1 in the whole transmission process
- In save mode: BSYFLG is kept low within one SCK clock cycle between transmission of each data

Note: It is best to use TXBEFLG and RXBNEFLG flags to process the transmitting and receiving of each data item.

#### 21.4.10.2 Error flag bit

#### Master mode error MEFLG

MEFLG is an error flag bit. The master mode error occurs when: in hardware NSS mode, the NSS pin of the master device is pulled down; in software NSS mode, ISSEL bit is cleared; MEFLG bit is set automatically.

Influence of master mode failure: MEFLG is set to 1, and SPI interrupt is generated when ERRIEN is set; SPIEN is cleared (output stops, SPI interface is closed); MSMSEL is cleared and the device is forced into the slave mode.

Operation of clearing the MEFLG flag bit: When MEFLG flag bit is set to 1, it is required to read or write SPI\_STS register, and then write to SPI\_CTRL1

register.

When the MEFLG flag bit is 1, it is not allowed to set the SPIEN and MSMSEL bits

#### Overrun error OVRFLG

Overrun error: After the master device Transmits the data, the RXBNEFLG flag bit is still 1, which indicates that the overrun error occurred. Then OVRFLG bit is set to 1, and if the ERRIEN bit is also set, an interrupt will be generated.

After an overrun error occurs, the data in the receive buffer is not the data sent by the master device, and then the read data in SPI\_DATA register is the data not read before, while the data sent later will not be read.

OVRFLG flag can be cleared by reading SPI\_DATA register and SPI\_STS register according to the sequence.

#### CRC error flag CRCEFLG

By setting CRCEN bit of SPI\_CTRL1 register, start CRC computing, CRC error flag, and check whether the received data is valid.

When the value sent by SPI\_TXCRC register does not match the value in SPI\_RXCRC register, a CRC error will be generated, and CRCEFLG flag bit in SPI\_STS register will be set to 1.

CRCEFLG can be cleared by writing 0 to CRCEFLG bit of SPI\_STS register.

| Interrupt<br>flag | Interrupt event                   | Enable<br>control bit | Clearing method  |
|-------------------|-----------------------------------|-----------------------|--|
| TXBEFLG           | Transmit buffer empty<br>flag     | TXBEIEN               | Write SPI_DATA register  |
| RXBNEFLG          | Receive buffer non-<br>empty flag | RXBNEIEN              | Read SPI_DATA register   |
| MEFLG             | Mastermode failure event          |                       | Read/Write SPI_STS<br>register, and then write<br>SPI_CTRL1 register |
| OVRFLG            | Overrun error flag                | ERRIEN                | Read SPI_DATA register,<br>and then read SPI_STS<br>register         |
| CRCEFLG           | CRC error flag                    |                       | Write 0 to CRCEFLG bit   |

## 22 Four-line Serial Peripheral Interface (QSPI)

This module applies only to APM32F103xB.

## 22.1 Introduction

QSPI is a serial data bus interface, which consists of clock (SCLK), chip select signal (CS), and four data lines (IO[0:3]). Connect single, double or four-line external SPI Flash storage media. The interface has four transmission modes: send and receive, send only, receive only, and EEPROM read. The transmission mode is controlled by software.

## 22.2 Main Characteristics

QSPI has programmable clock polarity and clock phase. Inegrate FIFO used for transmitting and receiving, with FIFO depth of 8, and FIFO bit width of 32-bit, with four transmission modes, support transmission of data frame from 1 bit to 16 bits, support hardware or software to control the chip selection signal line; in the four -line transmission mode, support clock extension, variable instruction length, address length, wait cycle, and data frame size; when receiving serial data, the programmable delay of sampling time can achieve higher sampling ratio of serial data bits.

## 22.3 Functional Description

## 22.3.1 Transfer Modes

This chapter discusses the operation of QSPI in different modes when data are transmitted on the serial bus. The transmission mode (TXMODE) is determined by TXMODE of the control register 1 (QSPI\_CTRL1).

## 22.3.2 Transmit and Receive

When TXMODE=2'b00, both transmit and receive logic are valid. When the data is written to the transmit FIFO and the number of data is greater than the FIFO transmitting watermark (TFTH of QSPI\_TFTL register), the transmission will start. The serial data is sent to the sending data line and reaches the target device. Meanwhile, The data on the receive data line will be sent from the receiving shift register to the receive FIFO.

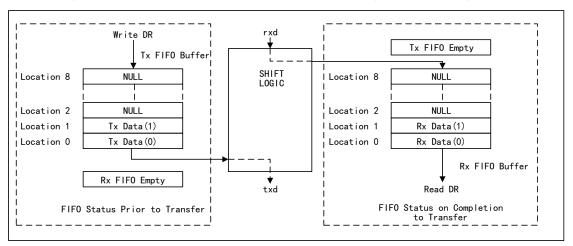

Figure 94 QSPI Transmit FIFO State in Transmitting and Receiving State

## **Transmit only**

When TXMODE=2'b01, only the transmitting logic unit is valid. The receiving logic unit is invalid, when the data is written to the transmit FIFO and the number of data is greater than the FIFO transmitting watermark (TFTH of QSPI\_TFTL register), the transmission will start, and the serial data will be sent to the transmitting data line and reach the target device. Data on the receive data line will be ignored. Therefore, no data is stored in the receive FIFO.

The following figure shows the FIFO level before the serial transfer starts and after the transfer is completed respectively. In this example, two data words are transferred from QSPI in a continuous transfer form to an external serial device.

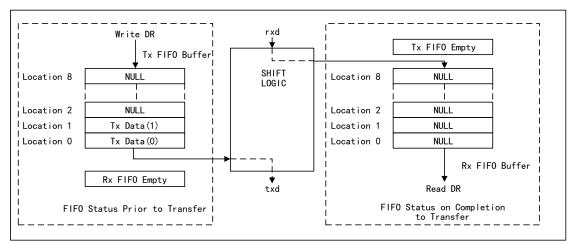

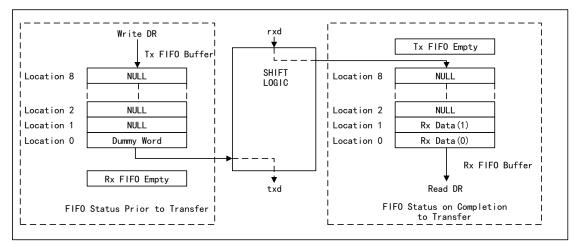

Figure 95 QSPI Transmit FIFO State in Transmitting State

## **Receive only**

When TXMODE=2'b10, only the receiving logic unit is valid, and the transmitting logic unit is invalid. No data will be sent. The data on the receive data line will be sent from the receiving shift register to the receive FIFO. To start a transmission, an invalid data should be written to the transmit FIFO.

The following figure shows the FIFO level before the serial transfer starts and after the transfer is completed respectively. In this example, QSPI continuously receives two data from an external serial device.

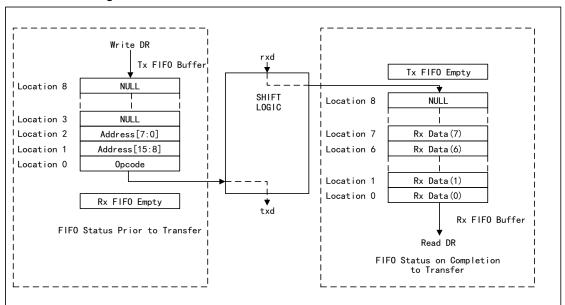

## Figure 96 QSPI Transmit FIFO State in Receive-only State

## 22.3.2.1 EEPROM (electrically erasable programmable read-only memory) read

When TXMODE=2'b11, the transmitted data is used to send the instruction/address to the corresponding external device. Three data frames (8-bit instruction code, 8-bit high address, and 8-bit low address) are usually required. In the process of transmitting data, the receiving logic unit will not capture any data on the receiving data line until the transmit FIFO is empty. Namely, when the transmit FIFO is empty, the receive logic unit starts to become effective and starts to receive data until the number of data frames received by QSPI is equal to the value of NDF field in QSPI\_CTRL2 register plus one.

The following figure shows the FIFO level before the serial transfer starts and after the transfer is completed respectively. In this example, QSPI continuously receives two data from an external serial device.

#### Figure 97 FIFO State in EEPROM Read Transmission Mode

## 22.3.3 Data Transfer

Data transfer is started by external master. After entering the transmit FIFO, the number of valid data will be more than the TFTH number of QSPI\_TFTL register, and an external slave device will be selected. When data is being transmitted, the register state is set as the BUSY flag. A new external transfer can be tried only after the BUSY flag is cleared.

## 22.3.4 Clock Ratio

## **Overview of clock ratios**

QSPI works in an oversampling structure. For the master mode of operation, the clock (sclk\_out) cycle of peripheral device is a multiple core clock (qspi\_clk).

## **Description of clock ratios**

When the QSPI macro cell is set as a master device, the maximum frequency (sclk\_out) of the bit rate clock is half the qspi\_clk frequency. This allows shift control logic to capture data at one clock edge of sclk\_out and derive data at the opposite edge.

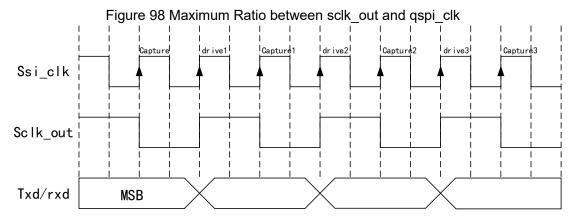

Sclk\_out frequency can be obtained from the following formula:

```
Fsclk out=Fssi CLK/SCKDIV
```

The SCKDIV programmable register is kept within a range with an average value of 0-65,534. Assuming SCKDIV=0, sclk\_out will be disabled.

sclk\_out line can be switched only when an active transfer is in progress. During the rest of the time, as defined by the serial protocol of its operation, it will stay idle.

The figure below shows the maximum ratio between sclk\_out and qspi\_clk.

## Overview of maximum ratios

The frequency ratio rule between (sclk\_out/sclk\_in) bit rate and QSPI peripheral device clock (qspi\_clk) is summarized as follows:

Fqspi\_clk>= 2× (maximum Fsclk\_out)

## 22.3.5 Receive and Transmit FIFO Buffers

#### Overview of receive and transmit FIFO buffers

The FIFO buffer used by QSPI is an internal Class-D trigger. The serial specification states that the length of a serial transfer (data frame) is 4-32 bits, so the length of transmit and receive FIFO buffer is fixed at 32 bits. Data frames less than 32 bits must be right aligned when they are written to the transmit FIFO buffer. The shift control logic will automatically right align the data received by the receive FIFO buffer. QSPI\_TFTL determines the level of FIFO entries that generate interrupts.

AHB sends the read instruction to QSPI data register (QSPI\_DATA) and the data will pop up from the receive FIFO. When the number of FIFO entries is greater than or equal to FIFO watermark plus 1, FIFO full interrupt request (qspi\_rxf\_intr) will occur to receive FIFO. The watermark that is set by the programmable register QSPI\_RFTL determines the level of FIFO entries that generate interrupts.

The watermark allows to send an instruction of which the FIFO will be empty to the processor. When the receive shift logic attempts to transfer data to the nearly full receive FIFO, an receive FIFO excess interrupt will be generated. Then, the newly received data will be lost. If you attempt to read data from an empty receive FIFO, a receive FIFO underrun interrupt will be generated. In such case, the processor will be warned that the read data is invalid.

## 22.3.6 Receive Data (RXD) Sampling Delay

#### Overview of receive data (RXD) sampling delay

When QSPI is set as the master, other logics can be included in the design to delay the default sampling time of the received data signal. Additional logic helps to increase the maximum achievable frequency of the serial bus.

#### Description of receive data (RXD) sample delay

The delay on the round-trip route between the sclk\_out signal issued by the master and the RXD signal sent by the slave can be considered as the timing of the received signal-as seen by the master-has left the normal sampling time. This situation is illustrated by the following legend:

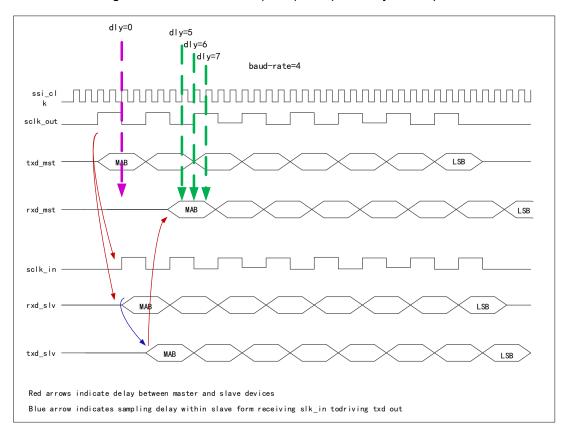

Figure 99 Received Data (RXD) Sample Delay Description

The slave uses the sclk\_out signal issued by the master as the gate in order to obtain the data of the RXD signal mapped to the serial bus. The Slave device's delay for the signal issued by sclk\_out in routing and sampling can mean that the RXD bit is not stable to the correct value before the master collects the RXD signal sample. The following figure shows how the routing delay of an RXD signal generates an incorrect RXD value at the default time of the master acquisition port. If there is no received sample delay logic, it is required to improve the baud rate of transfer to ensure that the installation time of the received data signal is within the range, which will result in reduction of the frequency of the serial interface.

When the RXD sample delay logic is included, the delay value can be dynamically edited to change the sampling time of RXD signal from the default value to the number of cycles of qspi\_clk. RXD sample delay logic can be set to

use both the positive and negative edges of qspi\_clk to collect RXD signal samples. This will increase the number of sampling points in one sclk\_out cycle, and help to satisfy timing of higher frequency. QSPI uses QSPI\_RSD register to change the sampling point of RXD signal.

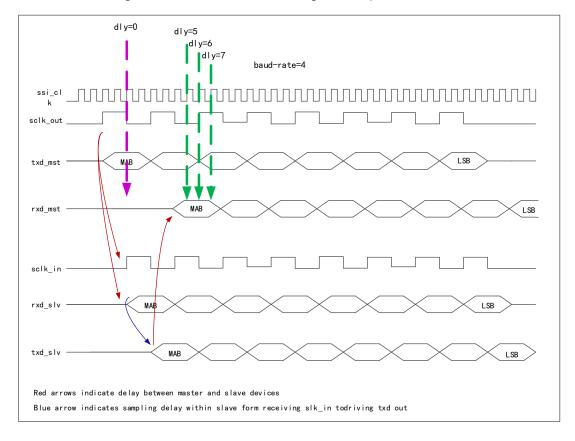

Figure 100 Collection of RXD Signal Samples with QSPI

## 22.3.7 QSPI Interrupt

## 22.3.7.1 QSPI interrupt description

## qspi\_txe\_intr

It is set when the transmit FIFO is less than or equal to its watermark. The watermark that is set by the programmable register QSPI\_RFTL determines the level of FIFO entries that generate interrupts. When data is written to the transmit FIFO buffer, the interrupt will be cleared by hardware to exceed the watermark level.

## qspi\_txo\_intr

It is set when an AHB access attempts to write to a fully written transmit FIFO. After set, the data written from AHB will be ignored. Before the transmit FIFO overrun interrupt clear register (QSPI\_TFOIC) is read, the interrupt still remains set.

## qspi\_rxf\_intr

When the receive FIFO is equal to or greater than its watermark, it will be set and the lower prevention service is required. The watermark that is set by the programmable register QSPI\_RFTL determines the level of FIFO entries that

generate interrupts. When data is read from the receive FIFO buffer, the interrupt will be cleared by hardware to exceed the watermark level.

#### qspi\_rxo\_intr

It is set when the receive logic attempts to put data in the fully written receive FIFO. When set, the newly received data will be ignored. Before the receive FIFO overrun interrupt clear register (QSPI\_RFOIC) is read, the interrupt still remains set.

#### qspi\_rxu\_intr

It is set when an AHB access attempts to read from an empty receive FIFO. After set, read as zero from the receive FIFO. Before the receive FIFO underrun interrupt clear register (QSPI\_RFUIC) is read, the interrupt still remains set.

#### qspi\_mst\_intr

Present only when the QSPI component is set as a serial master device. When the serial master on another serial bus selects the QSPI master as the serial slave and actively transfers data, the interrupt is set. This will notify the processor of possible contention on the serial bus. Before the multi-master interrupt clear register (QSPI MIC) is read, the interrupt still remains set.

## 22.3.8 Enhanced SPI Mode

#### 22.3.8.1 Enhanced SPI mode write operation

QSPI write operation can be divided into three phases, namely, instruction phase, address phase and data phase.

## The following register locations are used for a write operation

QSPI\_CTRL1 [FRF] specifies frame transmission format.

QSPI\_CTRL3 [INSLEN] specifies instruction length.

QSPI\_CTRL3 [ADDRLEN] specifies address length.

QSPI\_CTRL1 [DFS] specifies data length.

Only when both the instruction and address are written to the data register, QSPI will start a write transmission.

To initiate a Quad write operation, FRF of QSPI\_CTRL1 must be set to 10, which means that the type of transfer is set. For each write instruction, the data will be transferred in the specified format of FRF bit of QSPI\_CTRL1.

The followings are some possible situations of enhanced SPI mode write operation:

- Case A: Both the instruction and address are transmitted in standard SPI format
- Case B: The instruction is transmitted in standard format, while the address is transmitted in enhanced SPI format
- Case C: Both the instruction and address are transmitted in enhanced SPI format

## Enhanced SPI mode read operation

QSPI read operation can be divided into four phases, namely, instruction phase, address phase, wait cycle and data phase.

The wait cycle can be programmed with WAITCYC of QSPI\_CTRL3. The wait cycle is used to lock and change the slave mode, from input to output, and can vary with the devices. For a read operation, QSPI sends the instruction and control data at one time, and after receiving the NDF (QSPI\_CTRL2 register) number of data frame, disable the slave selection signal. To initiate a Quad read operation, FRF of QSPI\_CTRL1 is set to 00/01/10 respectively. This will set the type of transfer, and the data of each read instruction will be transferred in the specified form in FRF of QSPI\_CTRL1.

The followings are four possible situations of enhanced SPI mode write operation:

- Case A: Both the instruction and address are transmitted in standard SIP format
- Case B: The instruction is transmitted in standard format, while the address is transmitted in enhanced SPI format
- Case C: Both the instruction and address are transmitted in enhanced SPI format
- Case D:There is no instruction read and address read transmission

## **Clock extension function**

When QSPI and external SPI devices are transmitting data, since the software may not guarantee the timeliness of transmission, the transmit FIFO may be empty when QSPI is sending data, so no valid data can be sent and overrun error will occur. When receiving, the receive FIFO may be full, the subsequent data could not be received normally and overrun error will occur. To avoid the above problems, the software must abandon the transmission and restart a transmission. To handle the above problems, QSPI provides clock extension function. If the transmit FIFO is empty by the end of one transmission of sending data, QSPI will close the clock signal. When there are enough data (the data volume is higher than the transmit data watermark TFTH) in the transmit FIFO, QSPI will output the clock signal again and continue the transmission. If the receive FIFO has been full by the end of receiving of data, QSPI will close the clock signal until the data in the receive FIFO is read (the data volume is lower than the receive data watermark value QSPI RFTL). Set bit30 in QSPI CTRL3 register and the clock extension function can be enabled or disabled. If the clock extension function is enabled, the length of the transmitted data frame must be filled in the QSPI CTRL2 register.

## 22.4 Register Address Mapping

| Register name | Description                               | Offset address |
|---------------|---|----------------|
| QSPI_CTRL1    | Control register 1                        | 0x00           |
| QSPI_CTRL2    | Control register 2                        | 0x04           |
| QSPI_SSIEN    | Enable register                           | 0x08           |

## 23 **Controller area network (CAN)**

## 23.1 Full Name and Abbreviation Description of Terms

Table 83 Full Name and Abbreviation Description of Terms

| Full name in English     | English abbreviation |  |  |
|--------------------------|----------------------|--|--|
| First Input First Output | FIFO                 |  |  |
| Request                  | REQ                  |  |  |

## 23.2 Introduction

CAN is abbreviation of Controller Area Network, and is serial communication protocol of ISO international standardization and supports CAN Protocol 2.0A and 2.0B. In CAN protocol, the sender sends the message to all receivers in the form of broadcast. When the node receives the message, it will go through the filter group and decide whether the message is needed according to the identifier. This design saves the CPU overhead.

## 23.3 Main Characteristics

- (1) Support CAN protocol 2.0A and 2.0B
- (2) The maximum baud rate of communication is 1Mbit/s
- (3) Transmission function
  - There are three transmitting mailboxes
  - The priority of transmitting message can be configured
  - Record the transmission time
- (4) Receiving function
  - Have two receive FIFO with three depth levels
  - Have 14 filter groups.
  - Record the receiving time

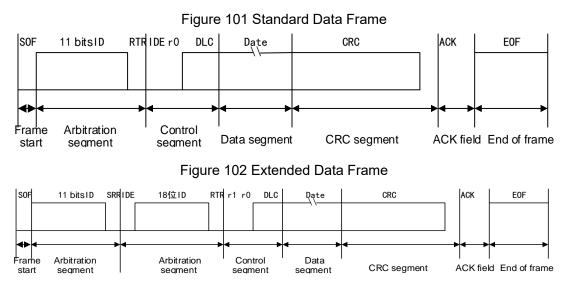

## 23.4 Functional Description

## 23.4.1 Characteristics of CAN Physical Layer

There can be multiple communication nodes on the CAN bus, each node consists of a CAN controller and a transceiver. The controller and transceiver are connected through CAN\_TX and CAN\_RX to transmit logic signals; the transceiver and bus are connected through CAN\_High and CAN\_Low to transmit differential signals.

## 23.4.2 Message Structure

Note:

- (1) Frame start: used to inform each node that there will be data for transmission.
- (2) Arbitration segment: It is used to decide which message can be transmitted when multiple messages are transmitted. Main content of this segment is ID information, the ID in standard format is 11 bits, and the ID in extended format is 29 bits.
- (3) Control segment: The main content of this segment is data length code (DLC), which is used to indicate how many bytes the data segment has in the message. The data segment has up to 8 bytes.
- (4) Data segment: Include the data information to be sent by the node.
- (5) CRC segment: CRC check code is used to ensure correct transmission of the messages.
- (6) ACK segment: This segment includes ACK slot bit and ACK delimiter bit. The transmitting node in ACK slot sends recessive bits, while the receiving node sends the dominant bit in this bit to acknowledge.
- (7) Frame end: Seven recessive bits sent by the transmitting nodes are used to indicate the end.

#### 23.4.3 Working Mode

CAN has three main working modes: initialization mode, normal mode and sleep mode.

#### 23.4.3.1 Initialization mode

Set the INITREQ bit of the configuration register CAN\_MCTRL to 1 to request to enter the initialization mode; clear the INITFLG bit to confirm entering the initialization mode.

Clear the INITREQ bit of the configuration register CAN\_MCTRL to request to exit the initialization mode; clear the INITFLG bit to confirm exiting the initialization mode.

Message receiving and transmitting is disabled in initialization mode.

#### 23.4.3.2 Normal mode

Clear the INITREQ bit of the configuration register CAN\_MCTRL through

software to request to enter the normal mode from the initialization mode; wait for the hardware to clear the INITFLG bit to enter the normal mode.

Message receiving and transmitting is allowed in normal mode.

## 23.4.3.3 Sleep mode

Set the SLEEPREQ bit of the configuration register CAN\_MCTRL to 1 to request to enter the sleep mode.

The clock of CAN stops work in sleep mode, the software can normally access the mailbox register, and the CAN is in low-power state.

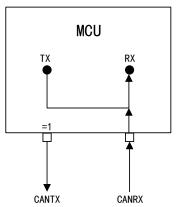

## 23.4.4 Communication Mode

There are four communication modes: silent mode, loopback mode, silent loopback mode and normal mode. Different communication modes can be selected only in initialization mode.

## 23.4.4.1 Silent mode

Set the SILMEN bit of the configuration register CAN\_BITTIM to 1 and select the silent mode.

In this mode, only recessive bit (logic 1)can be transmitted to the bus, while the dominant bit (logic 0) cannot be transmitted, and the data can be received from the bus.

## Figure 103 CAN Works in Silent Mode

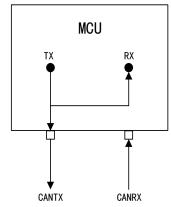

## 23.4.4.2 Loopback mode

Set the LBKMEN bit of the configuration register CAN\_BITTIM to 1 and select the loopback mode.

In this mode, the transmitted data are directly transmitted to the input end for receiving, the data are not received from the bus, and all data can be transmitted to the bus.

Figure 104 CAN Works in Loopback Mode

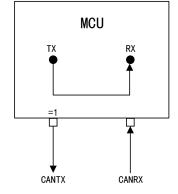

## 23.4.4.3 Loopback silent mode

Set the LBKMEN and SILMEN bits of the configuration register CAN\_BITTIM to 1 and select the loopback silent mode.

In this mode, the transmitted data are directly transmitted to the input end for receiving, and the data are not received from the bus; only recessive bit (logic 1) can be transmitted to the bus, while the dominant bit (logic 0) cannot be transmitted.

## 23.4.4.4 Normal mode

In this mode, data can be transmitted to the bus and be received from the bus.

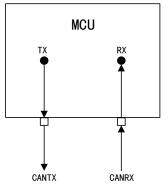

Figure 106 CAN Works in Normal Mode

## 23.4.5 Data Transmission

#### 23.4.5.1 Conversion of transmitting mailbox state

Conversion process of transmitting mailbox state:

- (1) First select an empty mailbox to set, submit the transmitting request to the CAN bus controller by setting the TXMREQ bit of the configuration register CAN\_TXMIDx to 1, and then the mailbox immediately enters the registration state.
- (2) When multiple mailboxes are in the registered state, conduct priority scheduling. When an mailbox has the highest priority, it will enter the predetermined state.
- (3) When the message in the transmitting mailbox is transmitted to the bus, it will enter the transmitting state.
- (4) After the message is transmitted successfully, the mailbox will become idle again.

#### 23.4.5.2 Transmitting priority

When multiple messages are waiting for transmitting, determine the transmitting sequence through the TXFPCFG bit of the configuration register CAN MCTRL:

- When the TXFPCFG bit is set to 0, the priority is determined by the message identifier, the identifier is the lowest, the priority is the highest, the identifier is equal, and the message with small mailbox number will be transmitted first
- When the TXFPCFG bit is set to 1, the priority will be determined by the sequence of transmitting request

#### 23.4.5.3 Abort

Transmit the abort request by setting the ABREQFLG bit of the configuration register CAN\_TXSTS to 1.

If the mailbox is in registered or predetermined state, stop transmitting the request immediately; if the mailbox is in the transmitting state, there are two conditions: one is that the mailbox is successfully transmitted, the mailbox becomes empty, in such case, the TXSUSFLG bit of the CAN\_TXSTS register is set to 1 by hardware; the other is that the mailbox fails to transmit, the mailbox becomes predetermined and the transmitting request is aborted.

#### 23.4.5.4 Automatic retransmission is disabled

Generally, in time triggered communication mode, automatic retransmission should be disabled.

In the mode that the automatic retransmission is disabled, the message is transmitted only once, and no matter what the result is (success, error or arbitration loss), the hardware will not transmit the message again automatically.

When the transmitting process is finished, set the REQCFLG bit of the CAN\_TXSTS register to 1, and the transmitting result will be on the TXSUSFLG, ARBLSTFLG and TXERRFLG bits

## 23.4.6 Data Receiving

#### 23.4.6.1 Receive FIFO

CAN has two receive FIFOs, each FIFO has three mailboxes, the FMNUM[1:0] bit of the register CAN\_RXF reflects the number of messages currently stored; set the RFOM bit to1 to release the output mailbox of receive FIFO; FFULLFLG is the full state flag bit; FOVRFLG is overrun state flag bit.

## 23.4.6.2 Receive FIFO state conversion

At the beginning FIFO is in empty state, and after receiving the message, it will become registered.

When FIFO is in registered state and three mailboxes are full, after receiving next effective message, it will enter the overrun state, and there are two situations for loss of messages in overrun state:

- If FIFO lock function is disabled, the finally received message will be covered by new message
- If FIFO lock function is enabled, the newly received message will be discarded

## 23.4.7 Filtering Mechanism

Function of the filter: The receiving node decides whether the message is needed according to the message identifier, and only the required message will be received after filtering. CAN controller has 14 filter groups.

## 23.4.7.1 Bit width

Each group of filters can configure two kinds of bit width.

#### Figure 107 One 32-bit Filter

| ID     | CAN_F i BANK1 [31 : 24] | CAN_F i BAN | IK1 [23 : 16] | CAN_FiBANK1[15:8] | CAN_FiBANK1[7:0] |                        |    |  |
|--------|-------------------------|-------------|---------------|-------------------|------------------|------------------------|----|--|
| mappin | g STDID[10:3]           | STDID[2:0]  | EXTID[17:13]  | EXTID[12:5]       | EXTID[4:0]       | IDTYP TXRFI<br>ESEL EQ | RO |  |

#### Figure 108 Two 16-bit Filters

| ID     | CAN_FiBANK1[15:8] | CAN_F i BANK1 [7:0] |  |                 | 0]               | CAN_FiBANK2[15:8] | CA             | CAN_F i BANK2 [7:0] |  |                  |
|--------|-------------------|---------------------|--|-----------------|------------------|-------------------|----------------|---------------------|--|------------------|
| mappin | g STDID[10:3]     | STDID<br>[2:0]      |  | I DT YP<br>ESEL | EXTID<br>[17:15] | STDID[12:5]       | STDID<br>[2:0] | TXRF<br>REQ         |  | EXTID<br>[17:15] |

## 23.4.7.2 Filtering mode

#### Mask bit mode

In this mode, it is only required to use some bits of the message identifier as a list to form the mask, and the message ID should be the same as the mask, and then the message can be received

| Table 8 | 34 N | Mask | Bit | Mode | Example | е |
|---------|------|------|-----|------|---------|---|
|---------|------|------|-----|------|---------|---|

| ID          | 1 | 0 | 1 | 1 | 0 | 0 | 1 | 0 |  |
|-------------|---|---|---|---|---|---|---|---|--|
| Mask        | 1 | 0 | 1 | 1 | 1 | 0 | 0 | 1 |  |
| Screened ID | 1 | Х | 1 | 1 | 0 | Х | Х | 0 |  |

## Identifier list mode

In this mode, each bit of the message ID needs to be the same as the filter identifier, and then the message can be received.

| ID          | 1 | 1 | 1 | 0 | 1 | 0 | 0 | 1 | 1 |
|-------------|---|---|---|---|---|---|---|---|---|
| ID          | 1 | 1 | 1 | 0 | 1 | 0 | 0 | 1 | 1 |
| Screened ID | 1 | 1 | 1 | 0 | 1 | 0 | 0 | 1 | 1 |

Table 85 Identifier List Mode Example

## 23.4.7.3 Filter priority

The priority rules are as follows:

- The priority of the filter with width of 32 bits is higher than that with width of 16 bits
- Under the condition of the same bit width, the priority of the identifier list mode is higher than that of mask bit mode
- Under the condition of the same bit width and mode, the priority of the small filtering number is high

## 23.4.8 Bit Timing and Baud Rate

## 23.4.8.1 Bit timing

The CAN peripheral bit timing of APM32 contains three segments: synchronization segment (SYNC\_SEG), time segment 1 (BS1) and time segment 2 (BS2), and the sampling points are at the junction of BS1 and BS2 segments.

- Synchronization segment (SYNC\_SEG): This bit occupies one time cell
- Time segment 1 (BS1): This segment occupies one to 16 time cells, and it contains PROP SEG and PHASE SEG1 in CAN standard
- Time segment 2 (BS2): This segment occupies one to eight time cells, and it represents PHASE\_SEG2 in CAN standard

## 23.4.8.2 Calculation of baud rate

Time of BS1 segment: Ts1=Tq\* (TIMSEG1[3:0]+1) Time of BS2 segment:Ts2=Tq\* (TIMSEG2[2:0]+1) Time of one data bit: T1bit=1Tq+Ts1+Ts2 Baud rate=1/ T1bit Tq = (BRPSC+1) \* TPCLK

## 23.4.9 Error Management

Transmit the error counter through the TXERRCNT bit of the configuration register CAN\_ERRSTS and receive the error counter through the RXERRCNT bit of the register CAN\_ERRSTS to reflect the error management of CAN bus.

Control the generation of interrupt in error state through the ERRIEN bit of the configuration register CAN\_INTEN.

## 23.4.9.1 Bus-off recovery

When the TXERRCNT of the CAN error state register is greater than 255, the CAN bus controller will enter the bus-off state, then the BOFLG bit of the register CAN\_ERRSTS is set to 1, and in this state, the CAN bus controller cannot receive and transmit messages.

Decide the bus-off recovery mode through the ALBOFFM bit of the configuration register CAN MCTRL:

- If the ALBOFFM bit is set to 1, once the hardware detects 11 continuous recessive bits for 128 times, it will exit the bus-off state automatically;
- If the ALBOFFM bit is set to 0, after the software requests to enter and then exit the initialization mode, it will exit the bus-off state.

## 23.4.10 Interrupt

## Events generating transmitting interrupt:

- The hardware sets REQCFLG0 bit of the register CAN\_TXSTS to 1, and the transmitting mailbox 0 becomes idle
- The hardware sets REQCFLG1 bit of the register CAN\_TXSTS to 1, and the transmitting mailbox 1 becomes idle
- The hardware sets REQCFLG2 bit of the register CAN\_TXSTS to 1, and the transmitting mailbox 2 becomes idle

## **Events generating FIFO0 interrupt:**

- Set the FMNUM0[1:0] bit of the register CAN\_RXF0 to a number rather than 0 by the hardware, and FIFO0 will receive a new message
- Set the FFULLFLG0 bit of the register CAN\_RXF0 to 1 by the hardware, and FIFO0 will be full
- Set the FOVRFLG0 bit of the register CAN\_RXF0 to 1 by the hardware and FIFO0 will overrun

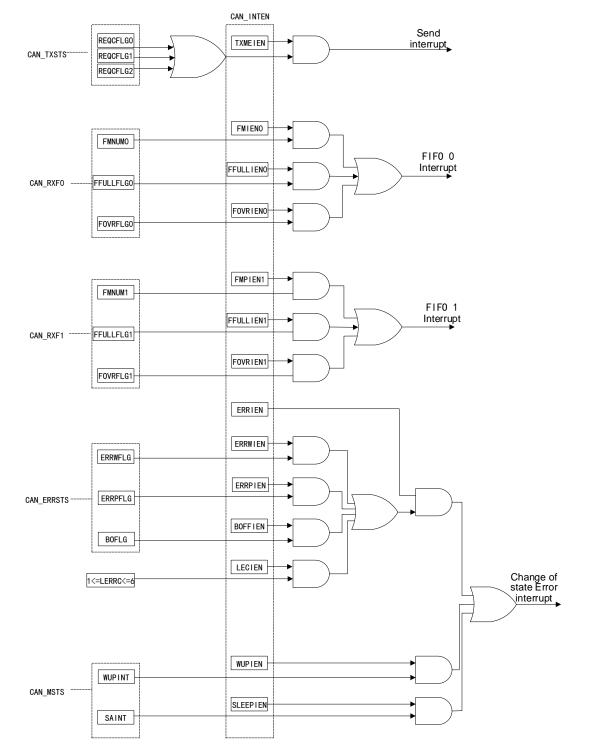

## Events generating FIFO1 interrupt:

- Set the FMNUM1[1:0] bit of the register CAN\_RXF1 to a number rather than 0 by the hardware, and FIFO1 will receive a new message
- Set the FFULLFLG1 bit of the register CAN\_RXF1 to 1 by the hardware, and FIFO1 will be full
- Set the FOVRFLG1 bit of the register CAN\_RXF1 to 1 by the hardware and FIFO1 will overrun

## Events generating state change and error interrupt:

- Set the SLEEPIEN bit of the register CAN\_INTEN to 1 by the hardware and it will enter the sleep mode
- Set the WUPIEN bit of the register CAN\_INTEN to 1 by the hardware and interrupt enable will be woken up
- Set the ERRWFLG bit of the register CAN\_ERRSTS to 1 by the hardware, and it means that the number of errors has reached the watermark
- Set the ERRPFLG bit of the register CAN\_ERRSTS to 1 by the hardware, and it means that the number of errors has reached the watermark of passive error
- Set the LERRC[2:0] bit of the register CAN\_ERRSTS by the hardware, and it indicates the condition of last error

## Figure 109 Event Flag and Interrupt Generation

## 23.5 Register Address Mapping

## Table 86 CAN Register Address Mapping

| Register name | Description               | Offset address |
|---------------|---------------------------|----------------|
| CAN_MCTRL     | CAN main control register | 0x00           |

| Register name | Description                                  | Offset address      |  |
|---------------|--|---------------------|--|
| CAN_MSTS      | CAN main state register                      | 0x04                |  |

| 31    | SILMEN   | R/W | Silent Mode Enable<br>0: Normal state<br>1: Silent mode |  |  |  |

Note: When CAN is in initialization mode, this register can be accessed only by software

#### 23.6.2 CAN mailbox register

This section describes the transmitting and receiving mailbox registers. The transmitting and receiving mailboxes are almost the same except the following examples:

- FMIDX domain of CAN\_RXDLENx register;
- The receiving mailbox is read-only;
- The transmitting mailbox is writable only when it is empty, and if the corresponding TXMEFLG bit of CAN\_TXSTS register is 1, it means the transmitting mailbox is empty.

There are three transmitting mailboxes and two receiving mailboxes in total. Each receiving mailbox is FIFO with three levels of depth, and can only access the message that is received first in FIFO.

#### 23.6.2.1 Transmitting mailbox identifier register (CAN\_TXMIDx) (x=0..2)

Offset address: 0x180, 0x190, 0x1A0

Reset value: 0xXXXX XXXX, X=undefined bit (except Bit 0, TXMREQ=0 after reset)

| Field | Name                     | R/W | Description   |
|-------|--------------------------|-----|---|
| 0     | TXMREQ                   | R/W | Transmit Mailbox Data Request<br>0: When the data in the mailbox is transmitted, the<br>mailbox is empty and this bit is cleared by hardware<br>1: Software writes 1, to enable request to transmit<br>mailbox data |
| 1     | TXRFREQ                  | R/W | Transmit Remote Frame Request<br>0: Data frame<br>1: Remote frame   |
| 2     | IDTYPESEL                | R/W | Identifier Type Select<br>0: Stanard identifier<br>1: Extended identifier   |
| 20:3  | EXTID[17:0]              | R/W | Extended Identifier Setup<br>Low byte of extended identity label.   |
| 31:21 | STDID[10:0]/EXTID[28:18] | R/W | Standard Identifier Or Extended Identifier<br>According to the content of IDTYPESEL bit, these bits<br>are standard identifier STDID[10:0] and high byte<br>EXTID[28:18] of extended identifier.                    |

Note: 1. When its mailbox is in the state of waiting for transmission, this register is write-protection

2. This register realizes transmission request control function (No. 0 bit) - the reset value is 0

#### 23.6.2.2 Transmitting mailbox data length register (CAN\_TXDLENx) (x=0..2) When the mailbox is not idle, all bits of this register are write-protected. Offset address: 0x184, 0x194, 0x1A4

Reset value: 0xXXXX XXXX

| Field | Name   | R/W | Description                     |  |
|-------|--------|-----|---------------------------------|--|
| 3:0   | DLCODE | R/W | Transmit Data Length Code Setup |  |

| Field | Name | R/W      | Description |  |
|-------|------|----------|-------------|--|
| 31:4  |      | Reserved |             |  |

#### 23.6.2.3 Transmitting mailbox low-byte data register (CAN\_TXMDLx) (x=0..2) When the mailbox is not idle, all bits of this register are write-protected, and the message contains 0 to 7-byte data and starts from the byte 0. Offset address: 0x188, 0x198, 0x1A8

Reset value: 0xXXXX XXXX

| Field | Name      | R/W | Description                |  |  |
|-------|-----------|-----|----------------------------|--|--|
| 7:0   | DATABYTE0 | R/W | Data Byte 0 of the Message |  |  |
| 15:8  | DATABYTE1 | R/W | Data Byte 1 of the Message |  |  |
| 23:16 | DATABYTE2 | R/W | Data Byte 2 of the Message |  |  |
| 31:24 | DATABYTE3 | R/W | Data Byte 3 of the Message |  |  |

#### 23.6.2.4 Transmitting mailbox high-byte data register (CAN\_TXMDHx) (x=0..2) When the mailbox is not idle, all bits of this register are write-protected. Offset address: 0x18C, 0x19C, 0x1AC

| Reset value: | Undefir | ned bit | - |
|--------------|---------|---------|---|
|              |         |         |   |

| Field | Name      | R/W | Description                |
|-------|-----------|-----|----------------------------|
| 7:0   | DATABYTE4 | R/W | Data Byte 4 of the Message |
| 15:8  | DATABYTE5 | R/W | Data Byte 5 of the Message |
| 23:16 | DATABYTE6 | R/W | Data Byte 6 of the Message |
| 31:24 | DATABYTE7 | R/W | Data Byte 7 of the Message |

#### 23.6.2.5 Receive FIFO mailbox identifier register (CAN\_RXMIDx) (x=0..1) Offset address: 0x1B0, 0x1C0

Reset value: Undefined bit

| Field | Name                     | R/W | Description  |
|-------|--------------------------|-----|--|
| 0     |                          |     | Reserved   |
| 1     | RFTXREQ                  | R   | Remote Frame Transmission Request<br>0: Data frame<br>1: Remote frame  |
| 2     | IDTYPESEL                | R   | Identifier Type Select<br>0: Stanard identifier<br>1: Extended identifier  |
| 20:3  | EXTID[17:0]              | R   | Extended Identifier Setup<br>Low byte of extended identifier.  |
| 31:21 | STDID[10:0]/EXTID[28:18] | R   | Standard Identifier Or Extended Identifier<br>According to the content of IDTYPESEL bit, these bits<br>are standard identifier STDID[10:0] and high byte<br>EXTID[28:18] of extended identifier. |

Note: All receiving mailbox registers are read-only.

#### 23.6.2.6 Receive FIFO mailbox data length register (CAN\_RXDLENx) (x=0..1) Offset address: 0x1B4, 0x1C4

#### Reset value: 0xXXXXX XXXX

| Field | Name     | R/W | Description  |  |  |
|-------|----------|-----|--|--|--|
| 3:0   | DLCODE   | R   | Receive Data Length Code Setup<br>This bit represents the data length in the frame; for remote frame,<br>DLCODE is constantly 0. |  |  |
| 7:4   | Reserved |     |  |  |  |
| 15:8  | FMIDX    | R   | Filter Match Index Setup   |  |  |
| 31:16 | Reserved |     |  |  |  |

Note: All receiving mailbox registers are read-only.

#### 23.6.2.7 Receive FIFO mailbox low-byte data register (CAN\_RXMDLx) (x=0..1)

Offset address: 0x1B8, 0x1C8; the message contains 0 to 8-byte data, which starts from the byte 0.

Reset value: 0xXXXXX XXXX

| Field | Name      | R/W | Description                |
|-------|-----------|-----|----------------------------|
| 7:0   | DATABYTE0 | R   | Data Byte 0 of the Message |
| 15:8  | DATABYTE1 | R   | Data Byte 1 of the Message |
| 23:16 | DATABYTE2 | R   | Data Byte 2 of the Message |
| 31:24 | DATABYTE3 | R   | Data Byte 3 of the Message |
|       |           |     |                            |

Note: All receiving mailbox registers are read-only.

#### 23.6.2.8 Receive FIFO mailbox high-byte data register (CAN\_RXMDHx) (x=0..1) Offset address: 0x1BC, 0x1CC

Reset value: Undefined bit

| Field | Name      | R/W | Description   |
|-------|-----------|-----|---|
| 7:0   | DATABYTE4 | R   | Data Byte 0 of the Message)                             |
| 15:8  | DATABYTE5 | R   | Data byte 5 of the message (Data Byte 0 of the Message) |
| 23:16 | DATABYTE6 | R   | Data byte 6 of the message (Data Byte 0 of the Message) |
| 31:24 | DATABYTE7 | R   | Data byte 7 of the message (Data Byte 0 of the Message) |

Note: All receiving mailbox registers are read-only.

#### 23.6.3 CAN filter register

#### 23.6.3.1 CAN filter control register (CAN\_FCTRL)

Offset address: 0x200

Reset value: 0x2A1C 0E01

| Field | Name    | R/W      | Description   |  |
|-------|---------|----------|---|--|
| 0     | FINITEN | R/W      | Filter Init Mode Enable<br>0: Normal mode<br>1: Initialization mode |  |
| 31:1  |         | Reserved |   |  |

Note: The non-reserved bit of this register is completely controlled by software.

#### 23.6.3.2 CAN filter mode configuration register (CAN\_FMCFG) Offset addres: 0x204

Reset value: 0x0000 0000

| Field | Name   | R/W      | Description   |  |
|-------|--------|----------|---|--|
| 13:0  | FMCFGx | R/W      | Filter Mode Configure<br>The value of x is within 0-13.<br>0: Identifier mask bit mode<br>1: Identifier list mode |  |
| 31:14 |        | Reserved |   |  |

Note: Only when CAN\_FCTRL (FINITEN =1) is set to make the filter in initialization mode, can this register be written.

#### 23.6.3.3 CAN filter bid width configuration register (CAN\_FSCFG) Offset address: 0x20C

Reset value: 0x0000 0000

| Field | Name   | R/W      | Description  |  |
|-------|--------|----------|--|--|
| 13:0  | FSCFGx | R/W      | Filterx Scale Configure<br>The value of x is within 0-13.<br>0: Two 16 bits<br>1: Single 32 bits |  |
| 31:14 |        | Reserved |  |  |

Note: Only when CAN\_FCTRL (FINITEN =1) is set to make the filter in initialization mode, can this register be written.

#### 23.6.3.4 CAN filter FIFO association register (CAN\_FFASS)

Offset address: 0x214 Reset value: 0x0000 0000

| Field | Name   | R/W | Description  |
|-------|--------|-----|--|
| 0     | FFASS0 | R/W | Configure Filter0 Associated with FIFO<br>0: The filter is associted with FIFO0<br>1: The filter is associted with FIFO1 |
| 1     | FFASS1 | R/W | Configure Filter1 Associated with FIFO<br>Refer to FFASS0 for specific description.                                      |
| 2     | FFASS2 | R/W | Configure Filter2 Associated with FIFO<br>Refer to FFASS0 for specific description.                                      |
| 3     | FFASS3 | R/W | Configure Filter3 Associated with FIFO<br>Refer to FFASS0 for specific description.                                      |
| 4     | FFASS4 | R/W | Configure Filter4 Associated with FIFO<br>Refer to FFASS0 for specific description.                                      |
| 5     | FFASS5 | R/W | Configure Filter5 Associated with FIFO<br>Refer to FFASS0 for specific description.                                      |
| 6     | FFASS6 | R/W | Configure Filter6 Associated with FIFO<br>Refer to FFASS0 for specific description.                                      |
| 7     | FFASS7 | R/W | Configure Filter7 Associated with FIFO<br>Refer to FFASS0 for specific description.                                      |
| 8     | FFASS8 | R/W | Configure Filter8 Associated with FIFO<br>Refer to FFASS0 for specific description.                                      |
| 9     | FFASS9 | R/W | Configure Filter9 Associated with FIFO<br>Refer to FFASS0 for specific description.                                      |

| Field | Name     | R/W | Description  |  |
|-------|----------|-----|--|--|
| 10    | FFASS10  | R/W | Configure Filter10 Associated with FIFO<br>Refer to FFASS0 for specific description. |  |
| 11    | FFASS11  | R/W | Configure Filter11 Associated with FIFO<br>Refer to FFASS0 for specific description. |  |
| 12    | FFASS12  | R/W | Configure Filter12 Associated with FIFO<br>Refer to FFASS0 for specific description. |  |
| 13    | FFASS13  | R/W | Configure Filter13 Associated with FIFO<br>Refer to FFASS0 for specific description. |  |
| 31:14 | Reserved |     |  |  |

Only when CAN\_FCTRL (FINITEN =1) is set to make the filter in initialization mode, can this Note: register be written.

## 23.6.3.5 CAN filter activation register (CAN\_FACT) Offset address: 0x21C Reset value: 0x0000 0000

| Field |          |     |  |  |  |  |
|-------|----------|-----|--|--|--|--|
| Field | Name     | R/W | Description  |  |  |  |
| 0     | FACT0    | R/W | Filter0 Active<br>0: Disable<br>1: Active                  |  |  |  |
| 1     | FACT1    | R/W | Filter1 Active<br>Refer to FACT0 for specific description  |  |  |  |
| 2     | FACT2    | R/W | Filter3 Active<br>Refer to FACT0 for specific description  |  |  |  |
| 3     | FACT3    | R/W | Filte3 Active<br>Refer to FACT0 for specific description   |  |  |  |
| 4     | FACT4    | R/W | Filter4 Active<br>Refer to FACT0 for specific description  |  |  |  |
| 5     | FACT5    | R/W | Filter5 Active<br>Refer to FACT0 for specific description  |  |  |  |
| 6     | FACT6    | R/W | Filte6 Active<br>Refer to FACT0 for specific description   |  |  |  |
| 7     | FACT7    | R/W | Filter7 Active<br>Refer to FACT0 for specific description  |  |  |  |
| 8     | FACT8    | R/W | Filter8 Active<br>Refer to FACT0 for specific description  |  |  |  |
| 9     | FACT9    | R/W | Filter9 Active<br>Refer to FACT0 for specific description  |  |  |  |
| 10    | FACT10   | R/W | Filter10 Active<br>Refer to FACT0 for specific description |  |  |  |
| 11    | FACT11   | R/W | Filter11 Active<br>Refer to FACT0 for specific description |  |  |  |
| 12    | FACT12   | R/W | Filter12 Active<br>Refer to FACT0 for specific description |  |  |  |
| 13    | FACT13   | R/W | Filter13 Active<br>Refer to FACT0 for specific description |  |  |  |
| 31:14 | Reserved |     |  |  |  |  |

#### 23.6.3.6 Register x of CAN filter group x (CAN\_FiBANKx) (i = 0..13; x=1..2)

#### Offset address: 0x240..0x2AC Reset value: 0xXXXX XXXX

| Field | Name       | R/W | Description  |
|-------|------------|-----|--|
| 31:0  | FBIT[31:0] | R/W | Filter Bits Setup<br>Identifier list mode:<br>0: FBITx bit is dominant bit<br>1: FBITx is recessive bit<br>Identifier mask bit mode:<br>0: FBITx is not used for comparison<br>1: FBITx must match<br>Note: The value of x is 0~31, indicating the bit number of FBIT. |

Note: There are 14 sets of filters in product: i=0..13. Each set of filters consists of two 32-bit registers and CAN\_FiBANK[2:1]. The corresponding filter registers can be modified only when the corresponding FACTx bit of CAN\_FACT register is cleared or the FINITEN bit of CAN\_FCTRL register is 1.

## 24 Full-speed USBD Interface Device (USBD)

### 24.1 Introduction

The peripheral meets the protocol standards and technical specifications of fullspeed USB2.0 interface device, and realizes the interface docking between USBD bus and APB1 bus. At the same time, the peripheral also has the functions of configurable up to 8 endpoints, synchronous transmission and endpoint double buffering mechanism, CRC check, USBD suspension/restoration operation and frame lock clock pulse generation.

Note: USBD1 and CAN share a dedicated 512-byte SRAM memory for data sending and receiving, and USBD2 and CAN each have a dedicated 512-byte SRAM memory for data sending and receiving. Therefore, USBD1 and CAN cannot be used at the same time, but USBD2 and CAN can be used at the same time, and then CAN needs remap. (Only applicable to APM32F103xB)

## 24.2 Functional Description

USBD module realizes the communication interface function between the MCU and the PC which conform to USB2.0 interface protocol. In the process of realizing this function, a shared private data buffer directly accessible to USBD peripheral is used. The size of this data buffer is determined by the number of configured endpoints and the maximum data packet size of different endpoints. Up to 8 bidirectional or 16 one-way endpoints can be used. Each endpoint can use 512 bytes at most. The format of data frame for USBD and PC communication is completed by hardware.

Different endpoints need to have an independent buffer description block, which is used to describe the buffer address, size and byte length of the transmitted data of the endpoint. By responding to the USBD interrupt, and judging the setting of the endpoint state register in the interrupt, the chip core enters different interrupt processing sub-functions, to process the services that the endpoint needs, and transmit corresponding types of data.

## 24.3 Register Address Mapping

| Register name    | Description  | Offset address        |
|------------------|--|-----------------------|
| USBD_CTRL        | USBD control register                                    | 0x40                  |
| USBD_INTSTS      | USBD interrupt state register                            | 0x44                  |
| USBD_FRANUM      | USBD frame state register                                | 0x48                  |
| USBD_ADDR        | USBD device address register                             | 0x4C                  |
| USBD_BUFFTB      | USBD packet buffer description table<br>address register | 0x50                  |
| USBD_SWITCH      | USBD switch register                                     | 0x100                 |
| USBD_EPn(n=[07]) | USBD endpoint n register                                 | From 0x00 to 0x1C     |
| USBD_TXADDRn     | Send buffer address register n                           | [USBD_BUFFTB]+n×16    |
| USBD_TXCNTn      | Send data byte number register n                         | [USBD_BUFFTB]+n×16+4  |
| USBD_RXADDRn     | Receive buffer address register n                        | [USBD_BUFFTB]+n×16+8  |
| USBD_RXCNTn      | Receive data byte number register n                      | [USBD_BUFFTB]+n×16+12 |

Table 87 USBD Register Address Mapping

## 24.4 Register Functional Description

The registers of USBD module have the following three categories:

- (1) General-purpose register: Interrupt register and control register;
- (2) Endpoint register: Endpoint configuration register and state register;
- (3) Buffer description table register: Register used to determine the packet storage address.

The base address of the buffer description table registers is specified by USBD\_BUFFTB register, and the base address of all other registers is the base address 0x4000 5C00 of USBD module. Since the APB1 bus is 32-bit addressable, the addresses of all 16-bit registers are aligned according to 32-bit word. The same address alignment method is also used for the packet buffer memory areas starting from 0x4000 6000.

#### 24.4.1 General-purpose Register

It is used to define the working mode of USBD module, interrupt processing, device address and reading of current frame number.

#### 24.4.1.1 USBD control register (USBD\_CTRL)

Offset address: 0x40 Reset value: 0x0003

| Field | Name     | R/W | Description   |  |
|-------|----------|-----|---|--|
| 0     | FORRST   | R/W | Force USBD Reset<br>Reset USBD by force, and before it is cleared by software, USBS<br>always remains in reset state.<br>0: Clear<br>1: Reset by force  |  |
| 1     | PWRDOWN  | R/W | Power Down<br>This mode is used to thoroughly close the USBD module. When this bit<br>is set to 1, the USBD module cannot be used.<br>0: Open<br>1: Closed  |  |
| 2     | LPWREN   | R/W | Lowpower Mode Enable<br>After this mode is turned on, when USBD is suspended, the system<br>clock will stop or decrease to a certain frequency, and other static<br>power consumption will be turned off except for the power supply of<br>external pull-up resistor.<br>Any wake-up event of USBD can clear this bit.<br>0: Normal mode<br>1: Low-power mode |  |
| 3     | FORSUS   | R/W | Force Suspend<br>When there is no data communication on USBD bus for 3ms, SUSP<br>interrupt will be triggered, then the software needs to set this bit to 1.<br>0: Invalid<br>1: Pend USBD by force   |  |
| 4     | WUPREQ   | R/W | Wakeup Request<br>Send the wake-up request to PC master. If this bit remains valid within<br>1ms to 15ms, the master will wake up the USBD.<br>0: Invalid<br>1: Valid   |  |
| 7:5   | Reserved |     |   |  |

| Field | Name     | R/W | Description  |
|-------|----------|-----|--|
| 8     | ESOFIEN  | R/W | Expected Start of Frame Interrupt Enable<br>0: Disable<br>1: Enable            |
| 9     | SOFIEN   | R/W | Start of Frame Interrupt Enable<br>0: Disable<br>1: Enable                     |
| 10    | RSTIEN   | R/W | USBD Reset Interrupt Enable<br>0: Disable<br>1: Enable                         |
| 11    | SUSIEN   | R/W | Suspend Mode Interrupt Enable<br>0: Disable<br>1: Enable                       |
| 12    | WUPIEN   | R/W | Wakeup interrupt Enable<br>0: Disable<br>1: Enable                             |
| 13    | ERRIEN   | R/W | Error interrupt Enable<br>0: Disable<br>1: Enable                              |
| 14    | PMAOUIEN | R/W | Packet Memory Area Over / Underrun Interrupt Enable<br>0: Disable<br>1: Enable |
| 15    | CTRIEN   | R/W | Correct Transfer Interrupt Enable<br>0: Disable<br>1: Enable                   |

#### 24.4.1.2 USBD interrupt state register (USBD\_INTSTS)

Offset address: 0x44

Reset value: 0x0000

The application program confirms the interrupt request event by reading the interrupt source state information of this register.

When an interrupt event occurs, the corresponding bit will be set by the hardware. If the corresponding bit in USBD\_CTRL is also set, an interrupt will be generated. After the interrupt is executed, the corresponding state bit will be cleared. It should be noted that when multiple interrupt flags are set, only one interrupt is generated.

USBD module has two-way interrupt request sources: high priority and low priority. The former interrupt request cannot be masked, while the latter can be masked. After identifying which endpoint the interrupt request is from, call the corresponding interrupt service program.

| Field | Name      | R/W | Description  |
|-------|-----------|-----|--|
| 3:0   | EPID[3:0] | R   | Endpoint Identifier<br>The application program reads the processing sequence of<br>interrupt request through software. The processing sequence is<br>determined by the endpoint number (the smaller the endpoint<br>number is, the higher the priority is). The priority is written by<br>hardware.  |
| 4     | DOT       | R   | Transmission direction (Direction of Transaction)<br>The application program reads this bit through the software to<br>learn the transmission direction of the pending interrupt, so as to<br>access the corresponding operation of CTFT or CTFR bit in<br>USBD_EPn, and this bit is written by hardware according to the<br>transmission direction. |

Each bit is described in detail below:

| Field | Name    | R/W   | Description   |
|-------|---------|-------|---|
|       |         |       | The IN packet means that the data are transmitted from the USBD module to the PC master, while the OUT packet is the opposite. When the packet is pending, it means the data transmission is completed.   |
|       |         |       | 0: The CTFT bit of the corresponding endpoint is set, which means that an IN packet is pending.   |
|       |         |       | 1: The CTFR bit of the corresponding endpoint is set, which means<br>that an OUT packet is pending. If the CTFT bit is set at the same<br>time, it means that both OUT packet and IN packet are pending at<br>the same time.                            |
| 7:5   |         |       | Reserved  |
| 8     | ESOFFLG | RC_W0 | Expected start of frame flag (Expected Start of Frame Flag)<br>When the USBD module does not receive the expected SOF<br>packet, it is set by hardware.<br>0: Clear<br>1: Failed to receive the expected SOF packet                                     |
|       |         |       | Start of frame flag (Start Of Frame Flag)   |
| 9     | SOFFLG  | RC_W0 | It indicates the start of a new USBD frame, and when the USBD<br>module detects the SOF packet on the bus, it will be set by<br>hardware.<br>0: Clear   |
|       |         |       | 1: SOF packet is detected   |
| 10    | RSTREQ  | RC_W0 | Reset request (USBD Reset Request)<br>The application program is readable and writable, only valid when<br>writing 0, and set by hardware.<br>0: Clear<br>1: Reset signal is detected   |
| 11    | SUSREQ  | RC_W0 | Module pending request (Suspend Mode Request)<br>It indicates a pending request from the USBD bus, which is set by<br>hardware when there is no signal transmission on the USBD line<br>for more than 3ms.<br>0: Clear<br>1: Pending interrupt occurred |
| 12    | WUPREQ  | RC_W0 | Wake-up request (Wakeup Request)<br>If the USBD module is pending and detects a wake-up signal, it<br>will be set by hardware.<br>0: Clear<br>1: Wake-up signal is detected   |
| 13    | ERRFLG  | RC_W0 | Transmission error interrupt (Failure Of Transfer Flag)<br>When NANS (master answer timeout)/CRC/BST (bit stuffing<br>error)/FVIO (frame format error) occurs, it is set by hardware.<br>0: Clear<br>1: Transmission error occurred                     |
| 14    | PMOFLG  | RC_W0 | Packet buffer overrun flag (Packet Memory Overflow Flag)<br>When the request to access the USBD packet buffer is sent but<br>the MCU does not respond for a long time, it will be set by<br>hardware.<br>0: Clear<br>1: Packet buffer overrun occurred  |
| 15    | CTFLG   | R     | Correct transfer flag (Correct Transfer Flag)<br>This bit is set by hardware after the endpoint completes data<br>transmission once correctly.<br>0: Meaningless<br>1: Data transmission is completed correctly   |

#### 24.4.1.3 USBD frame state register (USBD\_FRANUM)

Offset address: 0x48

#### Reset value: 0x0XXX; X means undefined value

| Field | Name         | R/W | Description   |
|-------|--------------|-----|---|
| 10:0  | FRANUM[10:0] | R   | Frame Sequence Number<br>Record the 11-bit frame code of the latest SOF packet, and the serial<br>number will automatically increase as the quantity of transmit frames<br>of the master increases. |
| 12:11 | LSOFNUM[1:0] | R   | Continuous Lost SOF Number<br>Record the number of SOF packets lost in the start of consecutive<br>frame, and this bit is cleared when the SOF packet is received again.                            |
| 13    | LOCK         | R   | Lock<br>If USBD continuously detects two or more SOP packets, it will be set<br>by hardware, then the frame counter will stop counting until the<br>USBD is reset or the bus is pending.            |
| 14    | RXDMSTS      | R   | Receive Data-Line Status<br>It indicates the state of USBD D- (Data minus) data line, and can<br>detect whether the wake-up condition appears in pending state.                                     |
| 15    | RXDPSTS      | R   | Receive Data+ Line Status<br>It indicates the state of USBD D+ (Data plus) data line, and can<br>detect whether the wake-up condition appears in pending state.                                     |

#### 24.4.1.4 USBD device address register (USBD\_ADDR)

## Offset address: 0x4C

| Resel value: 0x0000 |           |     |   |  |
|---------------------|-----------|-----|---|--|
| Field               | Name      | R/W | Description   |  |
| 6:0                 | ADDR[6:0] | R/W | Device Address<br>Record the address value assigned by USBD master for the device in<br>the process of enumeration. |  |
| 7                   | USBDEN    | R/W | USBD Enable<br>Enable USBD.<br>0: Disable<br>1: Enable  |  |
| 15:8                | Reserved  |     |   |  |

#### 24.4.1.5 USBD packet buffer description table address register (USBD\_BUFFTB) Offset address: 0x50

Reset value: 0x0000 0000

| Field | Name     | R/W | Description  |  |
|-------|----------|-----|--|--|
| 2:0   | Reserved |     |  |  |
| 15:3  | BUFFTB   | R/W | Buffer Table<br>Record the start address of the packet buffer description table. |  |
| 31:16 | Reserved |     |  |  |

#### 24.4.1.6 USBD switch register (USBD\_SWITCH)

Offset address: 0x100 Reset value: 0x0000

| Field | Name      | R/W | Description   |
|-------|-----------|-----|---|
| 0     | SWITCH[0] | R/W | USBD Switch<br>The default is 0.<br>0: USBD1 is used<br>1: USBD2 is used; then it can be used with CAN at the same time (Pins<br>PA11 and PA12 are used by USBD). |
| 15:1  | Reserved  |     |   |

#### 24.4.2 Endpoint Register

Each endpoint has corresponding USBD\_EPn (n=0...7) registers to store various state information of the endpoint.

#### 24.4.2.1 USBD endpoint n register (USBD\_EPn) (n=0 to 7)

Offset address: 0x00 to 0x1C

Reset value: 0x0000

When the endpoint register receives USBD bus reset or the FORRST of USBD\_CTRL is set, except that CTFT and CTFR bits remain unchanged for data transmission, other bits will be reset.

Each bit is described in detail below:

| Field | Name       | R/W   | Description  |
|-------|------------|-------|--|
| 3:0   | ADDR[3:0]  | R/W   | Endpoint Address<br>Before an endpoint is enabled, the application program must set<br>these four bits as an address.  |
| 5:4   | TXSTS[1:0] | т     | Status Bits for Transmission Transfers<br>This bit is used to identify the current state of the endpoint, and the<br>sending state code table indicates all states. The application<br>program is readable and writable; write 0 and this bit is invalid; write<br>1 to flip this bit.   |
|       |            |       | <ul><li>Data Toggle for Transmission Transfers</li><li>(1) For asynchronous endpoints, it is used to indicate the Toggle bit of the next data packet to be transmitted:</li><li>0: DATA0</li></ul>   |
| 6     | TXDTOG     | т     | <ol> <li>DATA1</li> <li>For double-buffer endpoints, it can be used for packet buffer exchange.</li> <li>For synchronous endpoints, as only DATA0 is transmitted, this bit is only used to support packet buffer exchange. The hardware sets the bit after receiving the data packet.</li> <li>The application program is readable and writable; write 0 and this bit is invalid; write 1 to flip this bit.</li> </ol> |
| 7     | CTFT       | RC_W0 | Correct Transfer Flag for Transmission<br>This bit is set by hardware after a correct IN packet is transmitted.<br>0: Clear this bit and it is meaningless to read out<br>1: IN packet is transmitted correctly. | 8     | KIND       | R/W   | Endpoint Kind<br>Please refer to the definition table of special types of endpoints for<br>specific definitions.   |
| 10:9  | TYPE       | R/W   | Endpoint Type<br>Please refer to the definition table of endpoint types for specific<br>definitions.   |
| 11    | SETUP      | R     | Setup Transaction Completed  |

| Field | Name   | R/W   | Description   |
|-------|--------|-------|---|
|       |        |       | It indicates whether the packet that currently completes transmission is SETUP packet. After the USBD module receives a correct SETUP packet, it is set by hardware.  |
|       |        |       | 0: No   |
|       |        |       | 1: Yes  |
|       |        |       | Note: This bit can be modified only when CTFR is 0, and cannot be modified when CTFR is 1.  |
|       |        |       | Status Bits for Reception Transfers   |
| 13:12 | RXSTS  | т     | This bit is used to identify the current state of the endpoint, and the receiving state code table indicates all states. The application program is readable and writable; write 0 and this bit is invalid; write 1 to flip this bit. |
|       |        |       | Data Toggle for Reception Transfers   |
|       |        |       | (1) For asynchronous endpoints, flag the Toggle bit of the next data<br>packet that is expected to be received, and it is set by hardware:  |
|       |        |       | 0: DATA0  |
|       |        |       | 1: DATA1  |
| 14    | RXDTOG | т     | (2) For control endpoint, after receiving the SETUP packet, it is cleared by hardware.  |
|       |        |       | (3) For double-buffer endpoints, it is used for the exchange of double buffers.   |
|       |        |       | (4) For synchronous endpoints, it is only used for the exchange of double buffers, without flipping.  |
|       |        |       | The application program is readable and writable; write 0 and this bit is invalid; write 1 to flip this bit.  |
|       |        |       | Correct receiving flag bit (Correct Transfer Flag for Reception)  |
|       |        |       | This bit is set by hardware after OUT or SETUP packet is received correctly.  |
| 15    | CTFR   | RC_W0 | 0: Clear  |
|       |        |       | 1: Packet is received correctly   |
|       |        |       | The application program is readable and writable; write 0 and this bit is valid; write 1 and this bit is invalid.   |

#### Table 88 Receive State Codes

| RXSTS[1:0] | Description   |
|------------|---|
| 00         | DISABLED: All receiving requests are ignored by the endpoint.           |
| 01         | STALL: The endpoint responds to all receive requests with STALL packet. |
| 10         | NAK: The endpoint responds to all receive requests with NAK packet.     |
| 11         | VALID: The endpoint can be used for receiving.                          |

#### Table 89 Endpoint Type Codes

| TYPE[1:0] | Description                   |  |  |  |
|-----------|-------------------------------|--|--|--|
| 00        | BULK: Bulk endpoint           |  |  |  |
| 01        | CONTROL: Control endpoint     |  |  |  |
| 10        | ISO: Synchronous endpoint     |  |  |  |
| 11        | INTERRUPT: Interrupt endpoint |  |  |  |

#### Table 90 Definition of Special Types of Endpoints

| The value of TYPE | Meaning of KIND                 |
|-------------------|---------------------------------|
| 00 (BULK)         | DBL_BUF: Double-buffer endpoint |
| 01 (CONTROL)      | STATUS_OUT                      |
| Other             | Unused                          |

#### Table 91 Transmit State Codes

| TXSTS | Description  |  |  |
|-------|--|--|--|
| 00    | DISABLED: All sending requests are ignored by the endpoint.          |  |  |
| 01    | STALL: The endpoint responds to all send requests with STALL packet. |  |  |
| 10    | NAK: The endpoint responds to all send requests with NAK packet.     |  |  |
| 11    | VALID: The endpoint can be used for sending.                         |  |  |

#### 24.4.3 Buffer Register

The buffer description table is located in the packet buffer to configure the address and size of the packet buffer shared by the USBD module and the MCU core.

#### 24.4.3.1 Transmit buffer address register n (USBD\_TXADDRn) (n=0 to 7) Offset address: [USBD\_BUFFTB]+n×16

Local address of USBD: [USBD\_BUFFTB]+n×8

| Field | Name | R/W      | Description   |  |
|-------|------|----------|---|--|
| 0     |      | Reserved |   |  |
| 15:1  | ADDR | R/W      | Transmission Buffer Address<br>Record the starting address of the buffer where the data to be sent<br>is located when the next IN packet is received. |  |

#### 24.4.3.2 Sending data byte number register n (USBD\_TXCNTn) (n=0 to 7) Offset address: [USBD\_BUFFTB]+n×16+4

| Local address | of USBD | : [USBD | BUFFTB | ]+n×8+2 |
|---------------|---------|---------|--------|---------|

| Field | Name     | R/W | Description  |
|-------|----------|-----|--|
| 9:0   | CNT      | R/W | Transmission Byte Count<br>This bit records the data byte count to be transmitted when<br>receiving next IN group. |
| 15:10 | Reserved |     |  |

Note: The double buffer and synchronous IN endpoint have two USBD\_TXCNT registers: USBD\_TXCNT\_1 and USBD\_TXCNT\_0, and the content is as follows:

| Field | Name   | R/W | Description   |  |
|-------|--|-----|---|--|
| 9:0   | CNT_0  | R/W | Transmission Byte Count0<br>Record the data byte count to be transmitted when receiving next<br>IN group. |  |
| 15:10 | Reserved   |     |   |  |
| 25:16 | CNT_1 R/W Record the data byte count to be transmitted when receiving next IN group. |     |   |  |
| 31:26 | 8 Reserved   |     |   |  |

#### 24.4.3.3 Receive buffer address register n (USBD\_RXADDRn) (n=0 to 7) Offset address: [USBD\_BUFFTB]+n×16+8 L

| _ocal addres | s of US | SBD: | [USBD_ | BUFFTB | ]+n×8+4 |
|--------------|---------|------|--------|--------|---------|
|              |         |      |        |        |         |

| Field | Name | R/W      | Description   |  |  |
|-------|------|----------|---|--|--|
| 0     |      | Reserved |   |  |  |
| 15:1  | ADDR | R/W      | Reception Buffer Address<br>Record the starting address of the buffer used to save data wher<br>receiving the next OUT or SETUP packet. |  |  |

#### 24.4.3.4 Receive data byte register n (USBD RXCNTn) (n=0 to 7)

Offset address: [USBD\_BUFFTB]+n×16+12

Local address of USBD: [USBD\_BUFFTB]+n×8+6

It is used to store two parameters that need to be used when receiving packets: the buffer size of receiving packets and the number of bytes actually received by USBD.

| Field | Name    | R/W | Description  |  |
|-------|---------|-----|--|--|
| 9:0   | CNT     | R   | Received byte number (Reception Byte Count)<br>It is written by the USBD module to record the actual number of<br>bytes of the latest OUT or SETUP packet received by the<br>endpoint. |  |
| 14:10 | BLKNUM  | R/W | Number of memory blocks (Number of Blocks)<br>Record the number of memory blocks allocated, which<br>determines the size of the packet buffer.   |  |
| 15    | BLKSIZE | R/W | Memory block size (Block Size)<br>Determine the size of memory block, which determines the   |  |

Note: The double buffer and synchronous IN endpoint have two USBD RXCNT registers: USBD RXCNT 1 and USBD RXCNT 0, and the content is as follows:

| Field | Name       | R/W | Description  |  |
|-------|------------|-----|--|--|
| 9:0   | CNT_0[9:0] | R   | Received byte number (Reception Byte Count)<br>Record the actual number of bytes of the latest OUT or SETUP<br>group received by the endpoint. |  |
| 14:10 | BLKNUM_0   | R/W | Number of memory blocks (Number of Blocks)   |  |
| 15    | BLKSIZE_0  | R/W | Memory block size (Block Size)<br>Determine the size of memory block.<br>0: Two bytes<br>1: 32 bytes   |  |
| 25:16 | CNT_1      | R   | Received byte number (Reception Byte Count)<br>Record the actual number of bytes of the latest OUT or SETUR<br>group received by the endpoint. |  |
| 30:26 | BLKNUM_1   | R/W | Number of memory blocks (Number of Blocks)<br>Record the number of memory blocks allocated.  |  |
| 31    | BLKSIZE_1  | R/W | Memory block size (Block Size)<br>Determine the size of memory block.<br>0: Two bytes<br>1: 32 bytes   |  |

| Value of BLKNUM[4:0] | Packet buffer size when<br>BLKSIZE=0 | Size of packet buffer when BLKSIZE=1 |
|----------------------|--------------------------------------|--------------------------------------|
| 00000                | Not allowed to use                   | 32byte                               |
| 00001                | 2 bytes                              | 64 bytes                             |
| 00010                | 4 bytes                              | 96 bytes                             |
| 00011                | 6 bytes                              | 128 bytes                            |
|                      |                                      |                                      |
| 01111                | 30 bytes                             | 512 bytes                            |
| 10000                | 32byte                               | Reserved                             |
| 10001                | 34 bytes                             | Reserved                             |
| 10010                | 36 bytes                             | Reserved                             |
|                      |                                      |                                      |
| 11110                | 60 bytes                             | Reserved                             |
| 11111                | 62 bytes                             | Reserved                             |

### 25.2 Introduction

Series products have two ADCs with 12-bit accuracy, and each ADC has up to 16 external channels and 2 internal channels. ADC1 and ADC2 have 16 external channels respectively, the A/D conversion mode of each channel has single, continuous, scan or discontinuous modes, and the ADC conversion results can be stored in 16-bit data register by left alignment or right alignment.

### 25.3 Main Characteristics

- (1) ADC power supply requirements: From 2.4V to 3.6V; the general power supply voltage is 3.3V.
- (2) ADC input range:  $V_{REF-} \leq V_{IN} \leq V_{REF+}$ .
- (3) 12-bit resolution
- (4) ADC conversion time
  - Formula: TCONV=samplting time+12.5 cycles
  - The sampling time is controlled by SMPCYCCFGx[2:0] bit, and the minimum sampling cycle is 1.5; when ADCCLK=14MHz, the sampling time is 1.5 cycles: TCONV=1.5 cycles +12.5 cycles=14 cycles=1 µs.
- (5) Mode input channel category
  - External GPIO input channel
  - One internal temperature sensor (VSENSE) input channel

- One internal reference voltage (VREFINT) input channel
- (6) Channel conversion mode
  - Single channel conversion mode: single conversion mode, continuous conversion mode
  - Input channel classification: regular channel, injected channel
  - One-group channel conversion mode: scan mode, discontinuous mode and injected channel management
  - ADC mode: Independent ADC mode, and dual ADC mode
- (7) Trigger mode
  - On-chip timer signal trigger
  - External pin signal trigger
  - Software trigger
- (8) Data register
  - Regular data register
  - Injected data register
- (9) Interrupt
  - End of conversion interrupt
  - Analog watchdog interrupt
- (10) DMA request supporting regular data conversion
- (11) Data alignment
  - Configurable data alignment of DALIGNCFG bit of data register ADC\_CTRL2 is left or right alignment.
- (12) Self-calibration
  - Enable calibration by setting CAL bit of ADC\_CTRL2 register. CAL bit is set to 1 during calibration and is cleared by hardware after calibration; calibration shall be performed every time before power-on.

## 25.4 Functional Description

#### 25.4.1 ADC Pins

| Table 94 ADC Pins               |  |  |  |  |
|---------------------------------|--|--|--|--|
| Name                            | Instruction  | Signal type                                      |  |  |
| V <sub>REF+</sub>               | High-end/Positive electrode reference voltage used by ADC, 2.4V≤V <sub>REF+</sub> ≤V <sub>DDA</sub>        | Input, analog<br>reference positive<br>electrode |  |  |
| V <sub>DDA</sub> <sup>(1)</sup> | Equivalent to analog power supply of V <sub>DD</sub> and:<br>2.4V≤V <sub>DDA</sub> ≤V <sub>DD</sub> (3.6V) | Input, analog power<br>supply                    |  |  |
| V <sub>REF-</sub>               | Low-end/Negative electrode reference voltage used by ADC, $V_{\text{REF-}}$ =V_{SSA}                       | Input, analog<br>reference negative<br>electrode |  |  |
| VSSA <sup>(1)</sup>             | Equivalent to analog power supply of $V_{ss}$  | Input, analog power<br>ground                    |  |  |
| ADCx_IN[15:0]                   | 16 analog input channels   | Analog input signal                              |  |  |

Note: 1.  $V_{DDA}$  and  $V_{SSA}$  should be connected to  $V_{DD}$  and  $V_{SS}$  respectively.

#### 25.4.2 ADC Conversion Mode

The product has multiple built-in ADCs and channels (refer to the data manual for the specific number), which can be combined into a variety of conversion

modes.

Multiple built-in ADCs; according to the number of ADCs, the conversion mode can be classified into independent ADC mode and dual ADC mode; multiple built-in channels, which can be classified into two groups, namely regular channel and injected channel. The internal conversion mode of each group can be divided into scan mode and discontinuous mode; for the internal channels of each group, the conversion mode is divided into single conversion mode and continuous conversion mode.

In the application, according to the actual application requirements, the number of ADC, the number of conversion channels and the conversion mode of each channel, the ADC conversion mode meeting the requirements can be designed.

#### 25.4.2.1 Conversion mode of single ADC and single channel

#### Single ADC channel

Single ADC and single channel are not enabled by external trigger software. The conversion mode is single and continuous concurrent disabling of scan. The result of data conversion is right alignment. After the single ADC conversion is completed, the interrupt is triggered, and data is read in the interrupt service function, not using DMA transmission.

#### Single conversion mode

In this mode, for single channel, only one conversion is performed for this channel, and for multiple channels, only one conversion is performed for this group of channels .

This mode is started by the ADCEN bit of configuration register ADC\_CTRL2 or is started by external trigger.

After one conversion of regular channel is over, the converted data will be stored in 16-bit ADC\_REGDATA register, and EOCFLG bit will be set to 1. If configuration EOCIEN bit is set to 1, an interrupt will be generated.

After one conversion of injected channel is over, the converted data will be stored in 16-bit ADC\_INJDATA1 register, and INJEOCFLG bit will be set to 1. If configuration INJEOCIEN bit is set to 1, an interrupt will be generated.

|                 | CH1 | CH1 | CH1 | CH1 |
|-----------------|-----|-----|-----|-----|
| Regular trigger |     |     |     |     |
| EOCFLG          |     |     |     |     |

#### Figure 110 Single Conversion Mode Timing Diagram

#### Continuous conversion mode

In this mode, for single channel, continuous conversion is conducted for this channel.

This mode is started by the ADCEN bit of configuration register ADC\_CTRL2 or is started by external trigger.

After the conversion of one regular channel is over, the converted data will be stored in 16-bit ADC\_REGDATA register, and EOCFLG bit will be set to 1. If configuration EOCIEN bit is set to 1, an interrupt will be generated.

After the conversion of one injected channel is over, the converted data will be stored in 16-bit ADC\_INJDATA1 register, and INJEOCFLG bit will be set to 1. If configuration INJEOCIEN bit is set to 1, an interrupt will be generated.

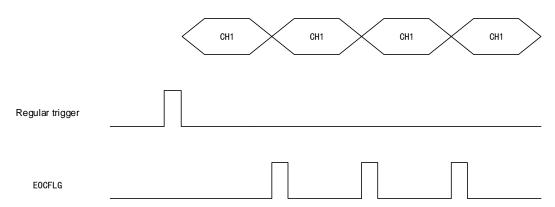

Figure 111 Continuous Conversion Mode Timing Diagram

#### 25.4.2.2 Conversion mode of single ADC and one group of channels

#### Single ADC and multiple channels

Enable the scan mode under single-ADC multi-channel condition, the conversion is triggered by software rather than externally, the result of data conversion is right aligned, and the data of ADC conversion results are transmitted to the memory by DMA.

#### **Classification of analog input channels**

#### Regular channel group

- The regular group consists of 16 channels
  - Regular channel conversion sequence is determined by the register ADC\_REGSEQx
  - The total number of conversion channels of regular group is determined by REGSEQLEN[3:0] bit of configuration register ADC\_REGSEQ1

#### Injected channel group

- The injected group consists of 4 channels
- Injected channel conversion sequence is determined by the register ADC\_INJSEQ
- The total number of conversion channels of injected group is determined by INJSEQLEN[1:0 bit of configuration register ADC\_INJSEQ

#### Internal input channel

Temperature sensor:

- The temperature sensor is used to measure the internal temperature of the chip
- The temperature sensor selects ADC\_IN16 input channel
- Start through TSVREFEN bit of the configuration register ADC\_CTRL2

Internal reference voltage V<sub>REFINT</sub>:

- The internal reference voltage is used to provide a stable voltage output for ADC
- Internal reference voltage V<sub>REFINT</sub> is used to select ADC\_IN17 input channel

#### Channel conversion sequence

#### Configuration of regular sequence registers:

- Configure REGSEQC1[4:0]~REGSEQC6[4:0] bits of the register ADC\_REGSEQ3 to set No. 1~6 conversion channels
- Configure REGSEQC7[4:0]~REGSEQC12[4:0] bits of the register ADC\_REGSEQ3 to set No. 7~12 conversion channels
- Configure REGSEQC13[4:0]~REGSEQC16[4:0] bits of the register ADC\_REGSEQ1 to set No. 13~16 conversion channels
- Configure REGSEQLEN[3:0] of the register ADC\_REGSEQ1 to set the number of channels for conversion

#### Configuration of injected sequence register:

- Configure NJSEQC1[4:0]~INJSEQC4[4:0] bit of the register ADC\_INJSEQ to set No. 1~4 conversion channels
- Configure INJSEQLEN[1:0] of the register ADC\_INJSEQ to set the number of channels for conversion
- If the value of INJSEQLEN is less than 4, the conversion sequence will be different and start from (4-INJSEQLEN).

#### **Channel conversion mode**

#### Scan Mode

This mode is applicable to one group of channels, which is equivalent to a single conversion on each channel of one group of channels.

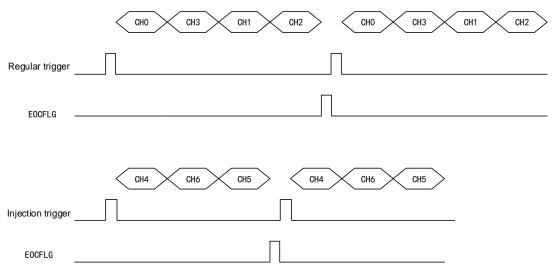

This mode is started by SCANEN bit of configuration register ADC\_CTRL1, and after startup, ADC scans all channels which are arranged according to the sequence register ADC\_REGSEQ or the ADC\_INJSEQ, and after each channel conversion is completed, it will be automatically converted to the next channel of the group.

If the configuration CONTCEN bit is set to 1, the conversion will continue from the first channel of the group when the last channel of the group completes conversion.

If the configuration DMAEN bit is set to 1, the DMA controller will transmit the converted data of regular channel to SRAM every time the channel conversion is completed.

#### Discontinuous mode

This mode is suitable for a group of channels, which is equivalent to continuous conversion of multiple channels in a group of channels.

For regular groups, this mode is started by REGDISCEN bit of configuration register ADC\_CTRL1; after startup, conduct short sequence conversion of n channels (n<=8), and n is determined by DISCNUMCFG[2:0] of configuration register ADC\_CTRL1; next round of conversion of n channels can be started through software control or external trigger source and when the conversion of all channels of this group is completed, EOCFLG bit will be set to 1.

For injected groups, this mode is enabled by INJDISCEN bit of configuration register ADC\_CTRL1; after startup, one channel will be converted according to the configuration sequence of the sequence register; conversion of next channels can be started by software control or external trigger source and when the conversion of all channels of this group is completed, EOCFLG bit and INJEOCFLG bit will be set to 1.

|                   | 0                           | 0 0            |
|-------------------|-----------------------------|----------------|

| Rule trigger      |                             |                |
| EOCFLG            |                             |                |
|                   |                             |                |
|                   | CH5         CH7         CH6 | СН5 СН7        |
| Injection trigger |                             |                |
| EOCFLG            |                             | 1              |

#### Figure 113 Discontinuous Mode Timing Diagram

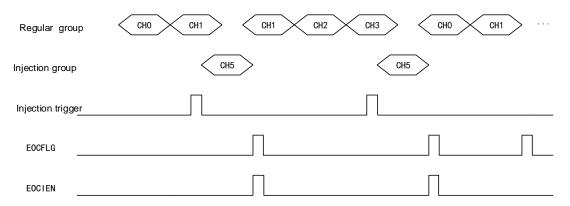

#### Injected channel management

www.geehy.com

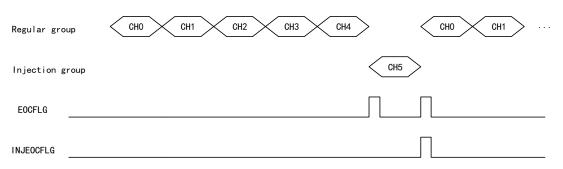

Trigger injection: Start by clearing INJGACEN bit of the register ADC\_CTRL1 and configuring the SCANEN bit. If a software trigger or external trigger is generated during the conversion of regular group channels, the injected conversion will be triggered. At this time, the regular channel conversion will stop, the injected channel sequence will start conversion, and after the injected group channel conversion is completed, the regular group channel conversion will be recovered.

Figure 114 Trigger Injection Timing Diagram

Automatic injection: Start by INJGACEN bit of configuration register ADC\_CTRL1; after conversion of the regular group channels is completed, the injected group channels will start conversion automatically; in the automatic injection mode, external trigger of the injected group channels must be disabled; if the CONTCEN bit of the register ADC\_CTRL2 is also configured, all channels of regular group and injection group will convert continuously.

Figure 115 Automatic Injection Timing Diagram

#### 25.4.2.3 Conversion mode of dual-ADC and one group of channels

Two ADC module products use dual-ADC mode, ADC1 is the master ADC by default, while ADC2 is the slave ADC by default; dual-ADC mode is set by configuring DUALMCFG[2:0] bit of the ADC1\_CTRL1 register.

When the configuration is triggered by external event, it is required to set it to trigger only the master ADC, and then configure the slave ADC to be triggered by software. (External trigger of master and slave must occur at the same time)

#### There are eight possible dual-ADC modes:

#### (1) Simultaneous regular mode

The simultaneous regular mode means ADC1 and ADC2 convert a regular channel group at the same time. Two ADCs cannot convert one channel at the same time.

The external trigger event is determined by REGEXTTRGSEL[2:0] of the register ADC1\_CTRL2.

After ADC conversion, DMA transmission request will be generated, and converted data of ADC1 are stored in low 16 bits of the register ADC1\_REGDATA, while ADC2 converted data are stored in high 16 bits of the register ADC1\_REGDATA.

EOCFLG interrupt will be generated after all ADC regular channels are converted.

#### (2) Simultaneous injection mode

The simultaneous injection mode means ADC1 and ADC2 convert one injected channel group at the same time. Two ADCs cannot convert one channel at the same time.

The external trigger event is determined by INJGEXTTRGSEL[2:0] of the register ADC1\_CTRL2.

After ADC conversion is over, the converted data will be stroed in the register ADC\_INJDATAx.

INJEOCFLG interrupt will be generated after all ADC injected channels are converted.

#### (3) Fast cross mode

The fast cross mode means ADC1 and ADC2 collect a regular channel group alternately, with a short interval time.

The external trigger event is determined by REGEXTTRGSEL[2:0] of the register ADC\_CTRL2; after the trigger is generated, ADC2 will be started, and ADC1 will be started after delay of seven ADC clock cycles.

The sampling time shall be less than seven ADC clock cycles.

#### (4) Slow cross mode

The slow cross mode means ADC1 and ADC2 collect a regular channel group alternately, with a long interval time.

The external trigger event is determined by REGEXTTRGSEL[2:0] of the register ADC\_CTRL2; after the trigger is generated, ADC2 will be started, and ADC1 will be started after delay of 14 ADC clock cycles.

The sampling time shall be less than 14 ADC clock cycles.

#### (5) Alternate trigger mode

The alternate trigger mode means ADC1 and ADC2 collect the injected channel group by turns.

The external trigger event is determined by INJGEXTTRGSEL[2:0] of the register ADC1\_CTRL2; after the trigger is generated, ADC1 will start conversion, and after all channels are converted, ADC2 will start conversion.

If discontinuous mode is enabled for ADC1 and ADC2, after triggered, ADC1 will start converting the first injected channel; after the second trigger is generated, ADC2 will start to convert the first injected channel and so on.

#### (6) Mixed simultaneous regular/injection mode

The mixed simultaneous regular/injection mode means after the simultaneous

regular mode is interrupted, the simultaneous injection mode will be enabled.

In this mode, a sequence of the same length must be converted or a trigger interval time must be set to complete the conversion of a longer sequence.

#### (7) Mixed simultaneous regular + alternate trigger mode

The mixed simultaneous regular + alternate trigger mode means after the simultaneous regular mode is interrupted, the alternate trigger mode will be enabled.

In this mode, a sequence of the same length must be converted or a trigger interval time must be set to complete the conversion of a longer sequence.

#### (8) Mixed simultaneous injection + cross mode

The mixed simultaneous injection + cross mode means after the cross regular mode is interrupted, the simultaneous injection mode will be enabled.

#### 25.4.3 External Trigger

Register configuration of external trigger is as follows:

- The external event trigger of regular group channel is enabled by REGEXTTRGSEL[2:0] bit of configuration register ADC\_CTRL2
- The external event trigger of injected group channel is started by INJGEXTTRGSEL[2:0] bit of configuration register ADC\_CTRL2.

Table 95 External Trigger of Regular Channel of ADC1 and ADC2

| Trigger source | REGEXTTRGSEL[2:0] | Trigger type                                       |
|----------------|-------------------|--|
| TMR1_CC1       | 000               |  |
| TMR1_CC2       | 001               |  |

| EINT Line 11   | 110               | External pin/internal signal from<br>on-chip timer |
| REGSWSC        | 111               | Software control bit                               |

Table 96 External Trigger of Injected Channel of ADC1 and ADC2

| Trigger source | INJGEXTTRGSEL[2:0] | Trigger type                                       |
|----------------|--------------------|--|
| TMR1_TRGO      | 000                |  |
| TMR1_CC4       | 001                |  |
| TMR2_TRGO      | 010                | Internal signal from an akin timor                 |
| TMR2_CC1       | 011                | Internal signal from on-chip timer                 |
| TMR3_CC4       | 100                |  |
| TMR4_TRGO      | 101                |  |
| EINT Line 15   | 110                | External pin/internal signal from<br>on-chip timer |
| INJSWSC        | 111                | Software control bit                               |

#### 25.4.4 Data register

#### 25.4.4.1 Regular data register

ADC\_REGDATA is a 32-bit ADC regular data register. In single-ADC mode, only the lower 16 bits are used to store the converted data. In dual-ADC mode, the lower 16 bits are used to store the converted data of ADC1 while the higher 16 bits are used to store the converted data of ADC2. The data are left aligned or right aligned.

It is determined by DALIGNCFG bit of configuration register ADC\_CTRL2 whether to use DMA transmission. There are at most 16 regular channels, but only one regular data register. Therefore, data coverage will occur in multi-channel conversion, and DMA transmission is needed at this time.

#### 25.4.4.2 Injection data memory

ADC\_INJDATAx (x=1,2,3,4) is ADC injected data register, and there are four 32bit registers, of which the low 16 bits are effective and the high 16 bits are reserved. There are at most four injected channels and four injection data registers, so data coverage will not occur in multi-channel conversion. The data are left aligned or right aligned.

#### 25.4.5 Interrupt

#### 25.4.5.1 End of conversion interrupt

#### Interrupt of end of conversion of regular group channels

An interrupt will be generated by the end of conversion of regular channels; read the value of the regular data register in the interrupt function.

Determine by EOCFLG bit of configuration register ADC\_STS.

#### Interrupt of end of conversion of injected group channels

An interrupt will be generated after the conversion of injected channels is completed; read the value of the regular data register in the interrupt function.

Determine by INJEOCFLG bit of configuration register ADC\_STS.

#### 25.4.5.2 Analog watchdog interrupt

If the input analog voltage is not within the watermark range, an analog watchdog interrupt will be generated.

Determine by configuring AWDFLG bit of the register ADC\_STS.

#### 25.4.6 DMA

DMA request will be generated after the conversion of regular channels is completed; the converted data result can be transmitted to the memory from the ADC\_REGDATA register.

ADC1 can generate DMA request, and the conversion results of ADC2 are transmitted through the DMA function of ADC1.

## 25.5 Register Address Mapping

 Table 97 ADC Register Address Mapping Table

| Register name | Description                                 | Offset address |
|---------------|---|----------------|
| ADC_STS       | ADC state register                          | 0x00           |
| ADC_CTRL1     | ADC control register 1                      | 0x04           |
| ADC_CTRL2     | ADC control register 2                      | 0x08           |
| ADC_SMPTIM1   | ADC sampling time register 1                | 0x0C           |
| ADC_SMPTIM2   | ADC sampling time register 2                | 0x10           |
| ADC_INJDOFx   | ADC injected channel data offset register x | 0x14-0x20      |
| ADC_AWDHT     | Analog watchdog high-watermark<br>register  | 0x24           |
| ADC_AWDLT     | Analog watchdog low-watermark register      | 0x28           |
| ADC_REGSEQ1   | ADC regular sequence register 1             | 0x2C           |
| ADC_REGSEQ2   | ADC regular sequence register 2             | 0x30           |
| ADC_REGSEQ3   | ADC regular sequence register 3             | 0x34           |
| ADC_INJSEQ    | ADC injected sequence register              | 0x38           |
| ADC_INJDATAx  | ADC injected data register X                | 0x3C-0x48      |
| ADC_REGDATA   | ADC regular data register                   | 0x4C           |

# 26 Cyclic Redundancy Check Computing Unit (CRC)

## 26.1 Introduction

The cyclic redundancy check (CRC) computing unit can get 32-bit CRC computing result by calculating the input data through a fixed generator polynomial, which is mainly used to detect or verify the correctness and integrity of the data after transmission or saving.

## 26.2 Functional Description

### 26.2.1 Calculation Method

Use CRC-32 (Ethernet) polynomial: 0x4C11DB7

 $(X^{32} + X^{26} + X^{23} + X^{22} + X^{16} + X^{12} + X^{11} + X^{10} + X^8 + X^7 + X^5 + X^4 + X^2 + X + 1)$ 

### 26.2.2 Calculation Time

The calculation time is four AHB clock cycles.

Every time a new data is written, the result will be a combination of the last calculation result and the new calculation result. (Execute operation for the whole word). Write operation of CPU will be suspended during calculation, so that "Back-to-back" write or continuous "read" -"write" operation can be performed for the register CRC\_DATA.

## 26.3 Register Address Mapping

| Register name | Description               | Offset address |
|---------------|---------------------------|----------------|
| DATA          | Data register             | 0x00           |
| INDATA        | Independent data register | 0x04           |
| CTRL          | Control register          | 0x08           |

Table 98 CRC Computing Unit Register Address Mapping

## 26.4 Register Functional Description

CRC computing unit contains two data memories and one control memory.

## 26.4.1 Data register (CRC\_DATA)

Offset address: 0x00 Reset value: 0xEEEE EEEE

| Field | Name | R/W | Description  |
|-------|------|-----|--|
| 31:0  | DATA | R/W | 32bit Data Register<br>It is used as a new data input port for CRC computing during<br>write operation; when the read operation is executed, the result<br>of CRC computing is returned. |

### 26.4.2 Independent data register (CRC\_INDATA)

Offset address: 0x04 Reset value: 0x0000 0000

| Field | Name   | R/W       | Description  |  |
|-------|--------|-----------|--|--|
|       |        |           | Independent 8bit Data  |  |
| 7:0   | INDATA | R/W       | It can be used to temporarily store 1-byte data; the CRC reset generated |  |
|       |        |           | by RST bit of the register CRC_CTRL has no effect on this register.      |  |
| 31:8  |        | Reserved. |  |  |

Note: This register does not take part in calculation and can store any data.

## 26.4.3 Control register (CRC\_CTRL)

Offset address: 0x08

| Field | Name | R/W | Description   |
|-------|------|-----|---|
|       |      |     | Reset CRC Calculation Unit  |
| 0     | RST  | W   | After reset, set the data register as 0xFFFF FFFF, and this bit can only be |
|       |      |     | written as 1 by software and automatically cleared by hardware.             |
| 31:1  |      |     | Reserved  |

## 27 Floating-point unit (FPU)

This module applies only to APM32F103xB.

## 27.1 Introduction

FPU (floating point unit) fully supports operations of single precision addition, subtraction, multiplication, division, multiplication, accumulation and square root. It also provides conversion between fixed-point and floating-point data formats, and floating-point constant instructions. FPU provides floating-point estimation function, which conforms to ANSI (American National Standards Institute)/IEEE (Institute of Electrical and Electronics Engineers) 754-2008 standard and IEEE binary floating-point algorithm standard , which is called IEEE 754 standard.

## 27.2 Functional Description

### 27.2.1 Supported Algorithms

FPU only supports single precision and supports IEEE754 compliance, including algorithms of: CMP, SUM, SUB, PRDCT, MAC, DIV, INVSQRT, SUMSQ, DOT, conversion from floating point to integer and conversion from integer to floating point.

| Term          | Definition   |
|---------------|--|
| I2FP          | Conversion from integer to floating point  |
| FP2I          | Conversion from floating point to integer  |
| CMP (p, q)    | Comparison of p and q  |
| SUM (p, n)    | $SUM(p,n) = \sum_{(i=0, n)} pi = p0 + p1 + + pi + + pn, 0 \le n \le 16$  |
| SUB (p, n)    | $SUB(p,n) = p0 - \sum_{(i=0, n)} pi = p0 - p1 pn, 0 \le n \le 16$  |
| PRDCT (p, n)  | Product: $PRDCT(p.n) = \prod_{(i=0,n)} pi = p0 * p1 * * pi * * pn, 0 \le n < 16$   |
| DIV (p, q)    | Division: $DIV(p,q) = \frac{p}{q}$   |
| INVSQRT (p)   | Square Root: INVSQRT (p) = $\frac{1}{\sqrt{p}}$  |
| MAC (p, q, s) | Floating-Point Multiply-Add: MAC (p, q, s) = $p * q + s$   |
| SUMSQ (p, n)  | $\sum$ (i=1, n) pi2, wherein p is the vector of the length n, 0≤n<16   |
| DOT (p, q, n) | ∑ (i=1, n) (pi * qi), whrein p and q are the vector of the length n, 0≤n<16  |
| SIN (x)       | $x \in (-\infty, +\infty)$ , wherein x is expressed in radian  |
| COS (x)       | $x \in (-\infty, +\infty)$ , wherein x is expressed in radian  |
| TAN (x)       | $x \in (-\infty, +\infty)$ , wherein x is expressed in radian  |
| ASIN (x)      | $x \in [-1,+1]$ , wherein the output value is expressed in radian, and is in the interval of $[-\pi/2, +\pi/2]$            |
| ACOS (x)      | $x \in [-1, +1]$ , wherein the output value is expressed in radian, and is in the interval of $[0, \pi]$                   |
| ATAN (x)      | $x \in [-\infty, +\infty]$ , wherein the output value is expressed in radian, and is in the interval of $[-\pi/2, +\pi/2]$ |
| ATAN2 (y, x)  | $x, y \in [-\infty, +\infty]$ , wherein the output value is expressed in radian, and is in the interval of $[-\pi, +\pi]$  |

| Table 99 FPU Su | pported Algorithm |
|-----------------|-------------------|

### 27.2.2 Software Programming

### 27.2.2.1 Programming process

It is recommended to use the relocatable library provided by us to connect the user program instead of programming on the basis of registers.

### 27.2.2.2 Single-operand operation

For FP2I, I2FP, INVSQRT, SIN, COS, TAN, ASIN, ACOS and ATAN, the recommended configuration is as follows:

- (1) Configure FPU\_CTRL register. Select the required operation mode and set the start (STR) bit. For INVSQRT mode, set the cycle index to improve the accuracy of FPU\_CTRL[7:6].
- (2) Write the operand to FPU\_FPI1
- (3) Flag of waiting for interrupt done or checking the FPU\_ISTS register done (DONE)
- (4) Read the result from FPU\_FPO

### 27.2.2.3 Operation of two operands

### For DIV, the recommended configuration is as follows:

- (1) Configure FPU\_CTRL register, select DIV mode and set the start (STR) bit.
- (2) Write the first operand to FPU\_FPI1
- (3) Write the second operand to FPU\_FPI1
- (4) Flag of waiting for interrupt done or checking the FPU\_ISTS register done (DONE)
- (5) Read the result from FPU\_FPO

### For CMP, the recommended configuration is as follows:

- (1) Configure FPU\_CTRL register, select CMP mode and set the start (STR) bit.
- (2) Write the first operand to FPU\_FPI1
- (3) Write the second operand to FPU\_FPI2
- (4) Flag of waiting for interrupt done or checking the FPU\_ISTS register done (DONE)
- (5) Read the CMP result from FPU\_ISTS[3:2]

### For ATAN2, the recommended configuration is as follows:

- (1) Configure FPU\_CTRL register, select ATAN2 mode and set the start (STR) bit.
- (2) Write the first operand to FPU\_FPI1
- (3) Write the second operand to FPU\_FPI2

- (4) Flag of waiting for interrupt done or checking the FPU\_ISTS register done (DONE)
- (5) Read the result from FPU\_FPO

### 27.2.2.4 Operation of three operands

### For MAC, the recommended configuration is as follows:

- (1) Configure FPU\_CTRL register, select MAC mode and set the start (STR) bit.
- (2) Write the first operand to FPU\_FPI1
- (3) Write the second operand to FPU\_FPI2
- (4) Write the third operand to FPU\_FPI2
- (5) Flag of waiting for interrupt done or checking the FPU\_ISTS register done (DONE)
- (6) Read the result from FPU\_FPO

### 27.2.2.5 Operation of n operands

## For SUM, SUB, PRDCT and SUMSQ, the recommended configuration is as follows:

- (1) Configure FPU\_CTRL register, select the required mode, enter the value of n in the nLEN field and set the start (STR) bit.
- (2) Write the P0 operand to FPU\_FPI1
- (3) Write the operand of P1..n-1 to FPU\_FPI2
- (4) Flag of waiting for interrupt done or checking the FPU\_ISTS register done (DONE)
- (5) Read the result from FPU\_FPO

### For DOT, the recommended configuration is as follows:

- (1) Configure FPU\_CTRL register, select DOT mode, enter the value of n in the nLEN field and set the start (STR) bit.
- (2) Write the P0 operand to FPU\_FPI1
- (3) Write the Q0 operand to FPU\_FPI2
- (4) Write the P1 operand to FPU\_FPI1
- (5) Write the Q1 operand to FPU\_FPI2
- (**6**) ...
- (7) Write the Pn-1 operand to FPU\_FPI1
- (8) Write the Qn-1 operand to FPU\_FPI2
- (9) Flag of waiting for interrupt done or checking the FPU\_ISTS register done (DONE)

(10) Read the result from FPU\_FPO

#### 27.3 **Register Address Mapping**

### Table 100 FPU Register Address Mapping

| Register name | Description                           | Offset address |
|---------------|---------------------------------------|----------------|
| FPU_CTRL      | Control register                      | 0x00           |
| FPU_ISTS      | Interrupt state register              | 0x04           |
| FPU_FPO       | Floating-point output value register  | 0x08           |
| FPU_FPI1      | Floating-point input value register 1 | 0x0C           |
| FPU_FPI2      | Floating-point input value register 2 | 0x10           |
| FPU_IM        | Interrupt mask register               | 0x14           |

| F | 31:12 | Reserved |     |             |

## 27.4.2 Interrupt state register (FPU\_ISTS)

Offset address: 0x4

| Field | Name      | R/W | Description   |  |
|-------|-----------|-----|---|--|
| 0     | DONE      | R/W | Flag of FPU Calculation Completion<br>0: FPU calculation uncompleted<br>1: FPU calculation completed  |  |
| 1     | BUSY      | R/W | FPU Busy Flag<br>0: FPU in idle state<br>1: FPU in busy state This bit can be set by hardware after FPU runs,<br>and automatically cleared by hardware after FPU completes calculation.       |  |
| 3:2   | CMPR[3:2] | R/W | Comparison SIgorithm Result<br>0: a = b <sub>o</sub><br>1: a < b <sub>o</sub><br>2: a > b <sub>o</sub><br>3: When one input value is not a number (NaN), it is unordered                      |  |
| 4     | ZERO      | R/W | Zero Flag<br>0: Meaningless.<br>1: The calculation result is zero or is zero after round-off  |  |
| 5     | INF       | R/W | Infinitely Great<br>0: Meaningless<br>1: The calculation result is infinitely great or is infinitely great after<br>round-off   |  |
| 6     | INVALID   | R/W | Floating-point Operation Is Invalid<br>0: Meaningless<br>1: Illegal input operation   |  |
| 7     | TINY      | R/W | The Calculation result Is Tiny<br>0: Meaningless.<br>1: After round-off, the floating point is a quantity less than the minimum<br>normalized number, but not an exact zero.                  |  |
| 8     | HUGE      | R/W | The Calculation Result Is Great.<br>0: Meaningless.<br>1: After round-off, the finite floating point result is a quantity greater than the maximum normalized number.                         |  |
| 9     | INEXACT   | R/W | The Calculation Result Is Not Accurate<br>0: Meaningless.<br>1: The integer or floating point output value is not equal to infinitely<br>great accurate result                                |  |
| 10    | HUGEINT   | R/W | Great Integer Complement<br>0: Meaningless<br>1: After round-off, the integer result is a quantity greater than the<br>maximum representable number of complement of two identical<br>symbols |  |
| 11    | DIVBY0    | R/W | Division by Zero<br>0: Meaningless<br>1: Run the operation of division by zero  |  |
| 31:12 | Reserved  |     |   |  |

### 27.4.3 Floating-point output value register (FPU\_FPO)

Offset address: 0x8

Reset value: 0x0000 0000

| Field | Name | R/W | Description                 |  |
|-------|------|-----|-----------------------------|--|
| 31:0  | FPO  | R   | Floating-point Output Value |  |

### 27.4.4 Floating-point input value register 1 (FPU\_FPI1)

Offset address: 0xC

Reset value: 0x0000 0000

| Field | Name | R/W | Description                  |
|-------|------|-----|------------------------------|
| 31:0  | FPI1 | R/W | Floating-point Input Value 0 |

## 27.4.5 Floating-point input value register 2 (FPU\_FPI2)

Offset address: 0x10

Reset value: 0x0000 0000

| Field | Name | R/W | Description                  |
|-------|------|-----|------------------------------|
| 31:0  | FPI2 | R   | Floating-point Input Value 1 |

### 27.4.6 Interrupt mask register (FPU\_IM)

Offset address: 0x14

| Field | Name     | R/W | Description  |  |
|-------|----------|-----|--|--|
| 0     | DONE     | R/W | Operation Completion Interrupt Mask<br>0: Operation completion interrupt enabled<br>1: Operation completion interrupt masked |  |
| 1     | INVALID  | R/W | Operation Interrupt Mask Invalid<br>0: Invalid operation interrupt enabled<br>1: Invalid operation interrupt masked          |  |
| 31:2  | Reserved |     |  |  |

## 28 Chip Electronic Signature

The chip electronic signature includes flash capacity information of main memory and 96-bit unique chip ID, which have been written into the system memory area of the chip before leaving the factory, and are read-only and can not be modified by users.

## 28.1 Capacity Register of Main Memory Area

### 28.1.1 Flash capacity register (16 bits)

Base address: 0x1FFF F7E0

Read-only, the value has been prepared before leaving the factory

| Field | Name   | R/W | Description   |
|-------|--------|-----|---|
|       |        |     | Flash memory capacity (Flash Size)                                |
| 15:0  | F_SIZE | R   | Indicate the capacity of main memory area of the product (in KB). |
|       |        |     | For example: 0x0080=128 KB  |

## 28.2 96-bit Unique Chip ID

Purposes of unique ID may be:

- As serial number (such as USBD character serial number or other terminal application)
- As a password; this unique identification can be used with software encryption and decryption algorithm to improve the security of the code in flash memory when writing the flash memory
- Used to activate the startup process with security mechanism
- The reference number provided by the identity is unique to any MCU series. Users cannot change the unique ID under no circumstances. According to different usage, users can choose to read the identity in byte, half word, or full word.

Base address: 0x1FFF F7E8 Offset address: 0x00

### Read-only, the value has been prepared before leaving the factory

| Field | Name       | R/W | Description                    |
|-------|------------|-----|--------------------------------|
| 15:0  | U_ID[15:0] | R   | Unique identity flag 15:0 bits |

Offset address: 0x02

### Read-only, the value has been prepared before leaving the factory

| Field | Name        | R/W | Description                     |
|-------|-------------|-----|---------------------------------|
| 15:0  | U_ID[31:16] | R   | Unique identity flag 31:16 bits |

### Offset address: 0x04

### Read-only, the value has been prepared before leaving the factory

| Field | Name        | R/W | Description                     |
|-------|-------------|-----|---------------------------------|
| 31:0  | U_ID[63:32] | R   | Unique identity flag 63:32 bits |

Offset address: 0x08

Read-only, the value has been prepared before leaving the factory

| Field | Name          | R/W | Description                     |
|-------|---------------|-----|---------------------------------|
| 31:0  | U_ID[95:64] R |     | Unique identity flag 95:64 bits |

## 29 Version History

| Date              | Version | Change History  |
|-------------------|---------|---|
| February 12, 2020 | 1.0     | New   |
| February 3, 2021  | 1.0     | Naming error of some registers                                  |
|                   |         | (1) Modify the reset value of "debug MCU device ID register" in |
| April 25 2021     | 1.1     | DBGMCU module   |
| April 25,2021     |         | (2) Modify TPYE of "USBD endpoint n register" to TYPE           |
|                   |         | (3) Modify GPIO section "Output Mode I/O Structure Diagram"     |
| July 21, 2021     | 1.2     | (1) Modify the 7:6 bit description of DBGMCU_CFG                |
| July 21, 2021     | 1.2     | (2) Modify the number of maskable interrupt channels            |
|                   |         | (1) Will be in the clock tree "4-16 MHZ LSICLK OSC" correction  |
| August 9, 2021    | 1.3     | for "4-16 MHZ HSECLK"   |
|                   |         | (2) Added details of APM32F103xB                                |
|                   |         | (1)Modify the contents of the CAN communication mode section    |
| March 15, 2022    | 1.4     | (2)Modify WDTSEL bit of Option Bytes in Flash module.           |
|                   |         | (3)Modify "SCLKSWSTS" to "SCLKSELSTS" in RCM.                   |
| June 30, 2022     | 1.5     | (1)Modify the Arm trademark                                     |
| Julie 30, 2022    | 1.5     | (2)Add the statement  |
|                   | 1.6     | (1) Modify the Reset registers and the Enable registers in RCM  |
| August 22, 2022   |         | module  |
|                   |         | (2) Delete the RGSQT function from the FPU                      |

### Table 101 Document Version History

## Statement

This document is formulated and published by Geehy Semiconductor Co., Ltd. (hereinafter referred to as "Geehy"). The contents in this document are protected by laws and regulations of trademark, copyright and software copyright. Geehy reserves the right to make corrections and modifications to this document at any time. Please read this document carefully before using Geehy products. Once you use the Geehy product, it means that you (hereinafter referred to as the "users") have known and accepted all the contents of this document. Users shall use the Geehy product in accordance with relevant laws and regulations and the requirements of this document.

### 1. Ownership

This document can only be used in connection with the corresponding chip products or software products provided by Geehy. Without the prior permission of Geehy, no unit or individual may copy, transcribe, modify, edit or disseminate all or part of the contents of this document for any reason or in any form.

The "极海" or "Geehy" words or graphics with "®" or "<sup>TM</sup>" in this document are trademarks of Geehy. Other product or service names displayed on Geehy products are the property of their respective owners.

#### 2. No Intellectual Property License

Geehy owns all rights, ownership and intellectual property rights involved in this document.

Geehy shall not be deemed to grant the license or right of any intellectual property to users explicitly or implicitly due to the sale or distribution of Geehy products or this document.

If any third party's products, services or intellectual property are involved in this document, it shall not be deemed that Geehy authorizes users to use the aforesaid third party's products, services or intellectual property, unless otherwise agreed in sales order or sales contract.

### 3. Version Update

Users can obtain the latest document of the corresponding models when ordering Geehy products.

If the contents in this document are inconsistent with Geehy products, the agreement in thesales order or the sales contract shall prevail.

### 4. Information Reliability

The relevant data in this document are obtained from batch test by Geehy Laboratory or cooperative third-party testing organization. However, clerical errors in correction or errors caused by differences in testing environment may occur inevitably. Therefore, users should understand that Geehy does not bear any responsibility for such errors that may occur in this document. The relevant data in this document are only used to guide users as performance parameter reference and do not constitute Geehy's guarantee for any product performance.

Users shall select appropriate Geehy products according to their own needs, and effectively verify and test the applicability of Geehy products to confirm that Geehy products meet their own needs, corresponding standards, safety or other reliability requirements. If loses are caused to users due to the user's failure to fully verify and test Geehy products, Geehy will not bear any responsibility.

### 5. Legality

USERS SHALL ABIDE BY ALL APPLICABLE LOCAL LAWS AND REGULATIONS WHEN USING THIS DOCUMENT AND THE MATCHING GEEHY PRODUCTS. USERS SHALL UNDERSTAND THAT THE PRODUCTS MAY BE RESTRICTED BY THE EXPORT, RE-EXPORT OR OTHER LAWS OF THE COUNTIRIES OF THE PRODUCTS SUPPLIERS, GEEHY, GEEHY DISTRIBUTORS AND USERS. USERS (ON BEHALF OR ITSELF, SUBSIDIARIES AND AFFILIATED ENTERPRISES) SHALL AGREE AND PROMISE TO ABIDE BY ALL APPLICABLE LAWS AND REGULATIONS ON THE EXPORT AND RE-EXPORT OF GEEHY PRODUCTS AND/OR TECHNOLOGIES AND DIRECT PRODUCTS.

6. Disclaimer of Warranty

THIS DOCUMENT IS PROVIDED BY GEEHY "AS IS" AND THERE IS NO WARRANTY OF ANY KIND, EITHER EXPRESSED OR IMPLIED, INCLUDING, BUT NOT LIMITED TO, THE WARRANTIES OF MERCHANTABILITY AND FITNESS FOR A PARTICULAR PURPOSE, TO THE EXTENT PERMITTED BY APPLICABLE LAW.

GEEHY WILL BEAR NO RESPONSIBILITY FOR ANY DISPUTES ARISING FROM THE SUBSEQUENT DESIGN OR USE BY USERS.

7. Limitation of Liability

IN NO EVENT UNLESS REQUIRED BY APPLICABLE LAW OR AGREED TO IN WRITING WILL GEEHY OR ANY OTHER PARTY WHO PROVIDE THE DOCUMENT "AS IS", BE LIABLE FOR DAMAGES, INCLUDING ANY GENERAL, SPECIAL, DIRECT, INCIDENTAL OR CONSEQUENTIAL DAMAGES ARISING OUT OF THE USE OR INABILITY TO USE THE DOCUMENT (INCLUDING BUT NOT LIMITED TO LOSS OF DATA OR DATA BEING RENDERED INACCURATE OR LOSSES SUSTAINED BY USERS OR THIRD PARTIES).

8. Scope of Application

The information in this document replaces the information provided in all previous versions of the document.
